## 8 Northeast Atlantic Mackerel

### 8.1 ICES Advice and International Management Applicable to 2018

From 2001 to 2007, the internationally agreed TACs covered most of the distribution area of the Northeast Atlantic mackerel. From 2008 to 2014, no agreement has been reached among the Coastal States on the sharing of the mackerel quotas. In 2014, three of the Coastal States (EU, NO and FO) agreed on a Management Strategy for 2014 to 2018. In November 2018, the agreement from 2014 was extended for two more years until 2020. However, the total declared quotas for 2015 to 2019 all exceed the TAC advised by ICES. An overview of the declared quotas and transfers for 2019, as available to WGWIDE, is given in the text table below. Total removals of mackerel are expected to be approximately 835000 t in 2019, exceeding the ICES advice for 2019 by about 65000 t .

| Estimation of 2019 catch | Tonnes | Reference |
| :--- | :--- | :--- |
| EU quota | 324195 | European Council Regulation2019/124 |
| Norwegian quota | 146832 | NEAFC HOD 19/02 |
| Inter-annual quota transfer 2018->2019 (NO) | -5601 | NEAFC HOD 19/02 |
| Russian quota | 108840 | Federal agencey for Fisheries, Russia |
| Inter-annual quota transfer 2018->2019 (RU) | 6152 | Federal agencey for Fisheries, Russia |
| Discards | 2890 | Previous years estimate |
| Icelandic quota | 131307 | Icelandic regulation No. 605/2019 |
| Faroese quota | 82339 | Faroese regulation No. 176/2018 |
| Greenland expected catch ${ }^{1}$ | 38000 | Ministry of Fisheries, Hunting and Agriculture in Greenland |
| Total expected catch (incl. discard) 2,3 | 834954 |  |

${ }^{11}$ Greenland quota for 2019 = 70411 t.
${ }^{2}$ No guesstimates of banking from 2019 to 2020
${ }^{3}$ Quotas refer to claims by each party for 2019

The quota figures and transfers in the text table above were based on various national regulations, official press releases, and discard estimates.

Various international and national measures to protect mackerel are in operation throughout the mackerel catching countries. Refer to Table 8.2.4.1 for an overview.

### 8.2 The Fishery

### 8.2.1 Fleet Composition in 2018

A description of the fleets operated by the major mackerel catching nations is given in Table 8.2.1.
The total fleet can be considered to consist of the following components:
Freezer trawlers. These are commonly large vessels (up to 150 m ) that usually operate a single mid-water pelagic trawl, although smaller vessels may also work as pair trawlers. These vessels are at sea for several weeks and sort and process the catch on board, storing the mackerel in frozen 20 kg blocks. The Dutch, German and the majority of the French and English fleets consist of these vessels which are owned and operated by a small number of Dutch companies. They fish in the North Sea, west of the UK and Ireland and also in the English Channel and further south along the western coast of France. The Russian summer fishery in Division 2.a is also prosecuted by freezer trawlers and partly the Icelandic fishery in Division 5.a and in some years in 14.b.

Purse seiners. The majority of the Norwegian catch is taken by these vessels, targeting mackerel overwintering close to the Norwegian coastline. The largest vessels ( $>20 \mathrm{~m}$ ) used refrigerated seawater (RSW), storing the catch in tanks containing refrigerated seawater (RSW). Smaller purse seiners use ice to chill their catch which they take on prior to departure. A purse seine fleet is also the most important component of the Spanish fleet. They are numerous and target mackerel early in the year close to the northern Spanish coast. These are dry hold vessels, chilling the catch with ice. Denmark also has a purse seine fleet operating in the northern North Sea.

Pelagic trawlers. These vessels vary in size from $20-100 \mathrm{~m}$ and operate both individually and as pairs. The largest of the pelagic trawlers use RSW tanks for storage. Iceland, Greenland, Faroes, Scotland and Ireland fish mackerel using pelagic trawlers. Scottish and Icelandic vessels mostly operate singly whereas Ireland and Faroes vessels tend to use pair trawls. Spain also has a significant trawler fleet which target mackerel with a demersal trawl in Subarea 8 and Division 9.a.N.

Lines and jigging. Norway and England have handline fleets operating inshore in the Skagerrak (Norway) and in Divisions 7.e/f (England) around the coast of Cornwall, where other fishing methods are not permitted. Spain also has a large artisanal handline fleet as do France and Portugal. A small proportion of the total catch reported by Scotland (Divisions $4 . a$ and 4.b) and Iceland (Division 5.a) is taken by a handline fleet.

Gillnets. Gillnet fleets are operated by Norway and Spain.

### 8.2.2 Fleet Behaviour in 2018

The northern summer fishery in Subareas 2, 5 and 14 continued in 2018. Fishing in the North Sea and west of the British Isles followed a traditional pattern, targeting mackerel on their spawning migration from the Norwegian deep in the northern North Sea, westwards around the north coast of Scotland and down the west coast of Scotland and Ireland.

The Russian freezer trawler fleet operates over a wide area in northern international waters. This fleet targets herring and blue whiting in addition to mackerel. In the third and fourth quarter of 2018 the Russian vessels took the vast majority of their catch in Division 2.a.

Total catches from Icelandic vessels were similar to those in recent years with the majority of the catch taken in Division 2.a in 2018. In 2017 the majority of the Icelandic catch was taken in 5.a in waters south and south-east of Iceland. Catches were also taken to the east and west of Iceland.

In 2018, Iceland and Greenland targeted mackerel in Division 14.b, with $6 \%$ of the total catch coming from this area. Catches from Greenland have increased in 2018 to almost 63 kt from 46 kt in 2017 and 30 kt in 2016 but are still lower than the 78 kt caught in 2014 which was the biggest catch by this fleet to date.

Concerning the Spanish fisheries, no new regulations have been implemented since 2010 when a new control regime was enforced. Fishery has started as in previous years at the beginning of March.

### 8.2.3 Recent Changes in Fishing Technology and Fishing Patterns

Northeast Atlantic mackerel, as a widely distributed species, is targeted by a number of different fishing métiers. Most of the fishing patterns of these métiers have remained unchanged during the most recent years, although the timing of the spawning migration and geographical distribution can change from year to year and this affects the fishery in various areas.

The most important changes in recent years are related to the geographical expansion of the northern summer fishery (Subareas 2,5 and 14) and changes in southern waters due to stricter TAC compliance by Spanish authorities.

As a result of this expansion, Icelandic vessels have increased effort and catch dramatically in recent years from 4 kt in 2006 to an average 160 kt annually since 2011. This fishery operates over a wide area E, NE, SE, S and SW off Iceland. Since 2011, there has been less fishing activity to the north and north-east and an increase in catches taken south and west of Iceland. Greenland has reported catches from Division $14 . b$ since 2011, and reached the biggest catch by this fleet to date in 2014, with a catch of 78 kt .

In 2010, the Faroese fleet switched from purse-seining in Norwegian and EU waters to pair trawling in the Faroese area. The Faroese fleet used to catch their mackerel quota in Divisions 4.a and 6.a during September-October with purse-seiners. However, as no agreement has been reached between the Coastal States since 2009, the mackerel quota has been taken in Faroese waters during June-October by the same fleet using pair trawls. The mackerel distribution is more scattered during summer and pair trawls seem to be effective in such circumstances. However, since the agreement between the three of the Coastal States for the fisheries in 2015, parts of the Faroese quota will now again be taken with purse-seines in Divisions 5.a and 6.a. In recent years, up to $25 \%$ of the Faroese quota have been granted to smaller, traditionally demersal trawlers using pair trawls.

In Spain, part of the purse seiner fleet is using hand lines instead of nets. Although, neither the number of vessels and its evolution nor the reason for such change were deeply analysed, it seems market reasons are driving this shift.

### 8.2.4 Regulations and their Effects

An overview of the major existing technical measures, effort controls and management plans are given in Table 8.2.4.1. Note that there may be additional existing international and national regulations that are not listed here.

Between 2010 and 2018 no overarching Coastal States Agreement/NEAFC Agreement was in place and no overall international regulation on catch limitation was in force. Currently there is no agreement on a management strategy covering all parties fishing mackerel. In 2014, three of the Coastal States (The EU, Faroes and Norway) agreed on a Management Strategy for 2015 and the subsequent five years. However, the total declared quotas taken by all parties since 2015 have greatly exceeded the TAC advised by ICES (see Section 8.1).

Management aimed at a fishing mortality in the range of $0.15-0.20$ in the period 1998-2008. The current management plan aims at a fishing mortality in the range $0.20-0.22$. The fishing mortality realised during $1998-2008$ was in the range of 0.27 to 0.46 . Implementation of the management plan resulted in a reduced fishing mortality and increased biomass. Since 2008 catches have greatly exceeded those given by the plan.

The measures advised by ICES to protect the North Sea spawning component aim at setting the conditions for making a recovery of this component possible. Before the late 1960s, the North Sea spawning biomass of mackerel was estimated at above 3 million tonnes. The collapse of mackerel in the North Sea in the late 1960s was most likely driven by very high catches and associated fishing mortality. However, the lack of recovery of mackerel in the North Sea was probably associated with unfavourable environmental conditions, particularly reduced temperatures (unfavourable for spawning), lower zoo-plankton availability in the North Sea and increased windstress induced turbulence. These unfavourable environmental conditions probably led the mackerel to spawn in western waters instead of in the North Sea.
A review of the mackerel in the North Sea, carried out during WKWIDE 2017 (ICES, 2017b) concluded that Northeast Atlantic mackerel should be considered as a single population (stock) with individuals that show stronger or weaker affinity for spawning in certain parts of the spawning area. Management should ensure that fisheries do not decrease genetic and behavioural diversity, since this could reduce future production. Protection of mackerel that tend to spawn in the north-eastern parts of the spawning area is therefore still advisable to some extent.

In the southern area, a Spanish national regulation affecting mackerel catches of Spanish fisheries has been implemented since 2010. In 2015, fishing opportunity was distributed by region and gear and for the bottom trawl fleet, by individual vessel. This year, Spanish mackerel fishing opportunity in Divisions 8.c and 9.a was established at 39674 t resulting from the quota established (Commission Regulation (EU) No 104/2015. This was reduced by 9797 t due to the scheduling payback quota due to overfishing of the mackerel quota allocated to Spain in 2010 (Commission Regulation No 976/2012).

Within the area of the southwest Mackerel Box off Cornwall in southern England only handliners are permitted to target mackerel. This area was set up at a time of high fishing effort in the area in 1981 by Council Regulation to protect juvenile mackerel, as the area is a well-known nursery. The area of the box was extended to its present size in 1989.
Additionally, there are various other national measures in operation in some of the mackerel catching countries.

The first phase of a landing obligation came into force in 2015 for all EU vessels in pelagic and industrial fisheries. All species that are managed through TACs and quotas must be landed under the obligation unless there is a specific exemption such as de minimis. There are de minimis exemptions for mackerel caught in bottom-trawl fisheries in the North Western Waters (EC 2018/2034) and in the North Sea (EC 2018/2035).

### 8.3 Quality and Adequacy of sampling Data from Commercial Fishery

The sampling of the commercial catch of North East Atlantic (NEA) mackerel is summarised below:
$\left.\begin{array}{llllll}\hline \text { Year } & \text { WG Total Catch } \\ \text { (t) catch covered } \\ \text { by sampling pro- } \\ \text { gramme* }\end{array} \quad \begin{array}{l}\text { No. } \\ \text { Samples }\end{array}\right)$

| Year | WG Total Catch |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| (t) | \% catch covered <br> by sampling pro- <br> gramme* | No. <br> Samples | No. | Noasured | Aged |
| 2016 | 1094066 | 89 | 2200 | 149216 | 21456 |
| 2017 | 1155944 | 87 | 2183 | 151548 | 24104 |
| 2018 | 1026437 | 83 | 1858 | 139590 | 20703 |

Overall sampling effort in 2018 was similar to previous years with $83 \%$ of the catch sampled. It should be noted that this proportion is based on the total sampled catch. Nations with large, directed fisheries are capable of sampling $100 \%$ of their catch which may conceal deficiencies in sampling elsewhere.

The 2018 sampling levels for countries with a WG catch of greater than 100 t are shown below.

| Country | Official catch | \% WG catch covered by sampling programme | No. Samples | No. <br> Measured | No. Aged |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Belgium | 168 | 0\% | 0 | 0 | 0 |
| Denmark | 30708 | 95\% | 6 | 449 | 450 |
| Faroe Islands | 81079 | 99\% | 15 | 871 | 921 |
| France | 21471 | 0\% | 0 | 0 | 0 |
| Germany | 19883 | 34\% | 84 | 716 | 17233 |
| Greenland | 63024 | 0\% | 0 | 0 | 0 |
| Iceland | 168330 | 98\% | 78 | 1910 | 3400 |
| Ireland | 66747 | 100\% | 42 | 1593 | 8254 |
| Netherlands | 30392 | 83\% | 28 | 775 | 2242 |
| Norway | 187207 | 92\% | 71 | 2345 | 2345 |
| Poland | 4057 | 0\% | 0 | 0 | 0 |
| Portugal | 4565 | 19\% | 148 | 492 | 7187 |
| Russia | 118255 | 95\% | 145 | 1342 | 36468 |
| Sweden | 3987 | 0\% | 0 | 0 | 0 |
| Spain | 35173 | 87\% | 1161 | 7200 | 35379 |
| UK (England \& Wales) | 20729 | 4\% | 47 | 1910 | 5234 |
| UK (Northern Ireland) | 14873 | 41\% | 1 | 53 | 203 |
| UK (Scotland) | 155380 | 99\% | 32 | 1047 | 4285 |

The majority of countries achieved a high level of sampling coverage. Belgian catches are bycatch in the demersal fisheries in the North Sea. France supplied a quantity of length-frequency data to the working group which can be utilised to characterise the selection of the fleet but requires an allocation of catch at age proportions from another sampled fleet in order to raise the data for use in the assessment. Greenland, with a WG catch of 63 kt did not provide any sampling information. Sweden and Poland did not supply sampling information in 2018. Portugal sampled landings from 9.a only. England only samples landings from the handline fleet operating off the Cornish coast, representing only a small proportion of the national catch, the remainder reported from freezer trawlers. Cooperation between the Dutch and German sampling programmes (which sampled $83 \%$ and $34 \%$ respectively) is designed to provide complete coverage for the freezer trawlers operating under these national flags and also those of England and France. Catch sampling levels per ICES Division (for those with a WG catch of $>100 \mathrm{t}$ ) are shown below.

| Division | Official Catch (t) | WG Catch (t) | No. Samples | No. Measured | No Aged |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2.a | 316662 | 316662 | 216 | 39528 | 3508 |
| 3.a | 552 | 552 | 2 | 50 | 50 |
| 4.a | 338056 | 338056 | 121 | 8908 | 3805 |
| 4.b | 2660 | 2660 | 4 | 340 | 161 |
| 4.c | 838 | 838 | 0 | 0 | 0 |
| 5.a | 65103 | 65103 | 31 | 1270 | 747 |
| 5.b | 11034 | 11034 | 3 | 158 | 149 |
| 6.a | 157275 | 157275 | 99 | 22006 | 1921 |
| 7.b | 10130 | 10130 | 10 | 1824 | 256 |
| 7.d | 5406 | 5406 | 3 | 192 | 154 |
| 7.e | 1131 | 1131 | 14 | 1442 | 942 |
| 7.f | 365 | 365 | 33 | 3792 | 968 |
| 7.9 | 159 | 159 | 0 | 0 | 0 |
| 7.h | 209 | 209 | 0 | 0 | 0 |
| 7.j | 8283 | 8283 | 10 | 1349 | 277 |
| 8.a | 5966 | 5966 | 1 | 1 | 1 |
| 8.b | 5002 | 5015 | 210 | 4414 | 303 |
| 8.c | 22884 | 22884 | 401 | 10450 | 3122 |
| 8.c.E | 8370 | 8749 | 186 | 16054 | 2320 |
| 8.d | 113 | 113 | 2 | 2 | 2 |

| Division | Official Catch (t) | WG Catch (t) | No. Samples | No. Measured | No Aged |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 9.a | 855 | 855 | 148 | 7187 | 492 |
| 9.a.N | 1881 | 1881 | 361 | 4458 | 1452 |
| 14.a | 107 | 62834 | 0 | 0 | 0 |
| 14.b | 62834 |  | 3 |  | 73 |

In general, areas with insufficient sampling have relatively low levels of catch. The exception is Division 7.d from which 5.5 kt (mainly French) was caught which was not sampled.

### 8.4 Catch Data

### 8.4.1 ICES Catch Estimates

The total ICES estimated catch for 2018 was 1026437 t , a decrease of 129507 t on the estimated catch in 2017. Catches increased substantially from 2006-2010 and have averaged 1081 kt since from 2011.

The combined 2018 TAC, arising from agreements and autonomous quotas, amounts to $998000 \mathrm{t})$. The ICES catch estimate ( 1026437 t ) represents an overshoot of this. The combined fishable TAC for 2019, as best ascertained by the Working Group (see Section 8.1), amounts to 834954 t.

Catches reported for 2018 and in previous Working Group reports are considered to be best estimates. In most cases, catch information comes from official logbook records. Other sources of information include catch processors. Some countries provide information on discards and slipped catch from observer programs, logbooks and compliance reports. In several countries discarding is illegal. Spanish data is based on the official data supplied by the Fisheries General Secretary (SGP) but supplemented by scientific estimates which are recorded as unallocated catch in the ICES estimates.

The text table below gives a brief overview of the basis for the ICES catch estimates.

| Country | Official Log Book | Other Sources | Discard Information |
| :--- | :--- | :--- | :--- |
| Denmark | Y (landings) | Y (sale slips) | Y |
| Faroe $^{1}$ | Y (catches) | Y (coast guard) | NA |
| France | Y (landings) | Y (landings) | Y |
| Germany | Y (catches) | Y (landings) | Y |
| Greenland | Y (landings) | Y |  |
| Iceland ${ }^{1}$ | Y (landings) | Y |  |
| Ireland |  | Y |  |
| Netherlands |  |  |  |

| Country | Official Log Book | Other Sources | Discard Information |
| :---: | :---: | :---: | :---: |
| Norway ${ }^{1}$ | Y (catches) |  | NA |
| Portugal |  | Y (sale slips) | Y |
| Russia ${ }^{1}$ | $Y$ (catches) |  | NA |
| Spain | Y | Y | Y |
| Sweden | Y (landings) |  | N |
| UK | Y (landings) | Y | Y |

${ }^{1}$ For these nations a discarding ban is in place such that official landings are considered to be equal to catches.
The Working Group considers that the estimates of catch are likely to be an underestimate for the following reasons:

- Estimates of discarding or slipping are either not available or incomplete for most countries. Anecdotal evidence suggests that discarding and slipping can occur for a number of reasons including high-grading (larger fish attract a premium price), lack of quota, storage or processing capacity and when mackerel is taken as by-catch.
- Confidential information suggests substantial under-reported landings for which numerical information is not available for most countries. Recent work has indicated considerable uncertainty in true catch figures (Simmonds et al., 2010) for the period studied.
- Estimates of the magnitude and precision of unaccounted mortality suggests that, on average for the period prior up to 2007, total catch related removals were equivalent to 1.7 to 3.6 times the reported catch (Simmonds et al., 2010).
- Reliance on logbook data from EU countries implies (even with $100 \%$ compliance) a precision of recorded landings of $89 \%$ from 2004 and $82 \%$ previous to this (Council Regulation (EC) Nos. 2807/83 \& 2287/2003). Given that over reporting of mackerel landings is unlikely for economic reasons; the WG considers that the reported landings may be an underestimate of up to $18 \%$ ( $11 \%$ from 2004), based on logbook figures. Where inspections were not carried out there is a possibility of a $56 \%$ under reporting, without there being an obvious illegal record in the logsheets. Without information on the percentage of the landings inspected it is not possible for the Working Group to evaluate the underestimate in its figures due to this technicality. EU landings represent about $65 \%$ of the total estimated NEA mackerel catch.
- The accuracy of logbooks from countries outside the EU has not been evaluated by WGWIDE. Monitoring of logbook records is the responsibility of the national control and enforcement agencies.

The total catch as estimated by ICES is shown in Table 8.4.1.1. It is broken down by ICES area group and illustrates the development of the fishery since 1969.

## Discard Estimates

With a few exceptions, estimates of discards have been provided to the Working Group for the ICES Subareas and Divisions 6, 7/8.a,b,d,e and 3/4 (see Table 8.4.1.1) since 1978. Historical discard estimates were revised during the data compilation exercise undertaken for the 2014 benchmark assessment (ICES, 2014). The Working Group considers the estimates for these areas are incomplete. In 2018, discard data for mackerel were provided by The Netherlands, France, Germany, Ireland, Spain, Portugal, Greenland, Denmark, England, Scotland and Sweden. Total discards amounted to 2890 t from the southern area. The German, French, Dutch, Irish and Portuguese
pelagic discard monitoring programmes did not record any instances of discarding of mackerel. Estimates from the other countries supplying data include results from the sampling of demersal fleets.

Age-disaggregated data was limited but data available indicates that, in Divisions 8.a, 8.b and 8.c the majority of discarded fish were aged 0 to 3. In Division 9.a the majority of the discarded fish were 0 group.

Discarding of small mackerel has historically been a major problem in the mackerel fishery and was largely responsible for the introduction of the south-west mackerel box. In the years prior to 1994, there was evidence of large-scale discarding and slipping of small mackerel in the fisheries in Division 2.a and Sub-area 4, mainly because of the very high prices paid for larger mackerel (>600 g) for the Japanese market. This factor was put forward as a possible reason for the very low abundance of the 1991 year class in the 1993 catches. Anecdotal evidence from the fleet suggests that since 1994, discarding/slipping has been reduced in these areas.

In some of the horse mackerel directed fisheries, e.g. those in Subareas 6 and 7, mackerel is taken as by-catch. Reports from these fisheries have suggested that discarding may be significant because of the low mackerel quota relative to the high horse mackerel quota, particularly in those fisheries carried out by freezer trawlers in the fourth quarter. The level of discards is greatly influenced by the market price and by quotas.

### 8.4.2 Distribution of Catches

A significant change in the fishery took place between 2007 and 2009 with a greatly expanded northern fishery becoming established, and maintained to the present. Of the total catch in 2018, Norway accounted for the greatest proportion (18\%) followed by Scotland (15\%), Iceland (16\%), Russia ( $12 \%$ ) and Faroe (8\%). In the absence of an international agreement, Greenland, Iceland and Russia declared unilateral quotas in 2018. Russia and Iceland both had catches over 100 kt with Faroes catching 81 kt . Greenlandic catches increased to almost 63 kt . Scotland had catch in excess of 100 kt and Ireland caught almost 67 kt . The Netherlands, Spain and Denmark had catches of around 30 kt while Germany, France and England had catches of the order of 20 kt .

In 2018, catches in the northern areas (Subareas 2, 5, 14) amounted to 455740 t (see Table 8.4.2.1), a decrease of 148129 t on the 2017 catch. Icelandic, Norwegian and Russian catches were all over 100 kt . Catches from Division 2.a accounted for $31 \%$ of the total catch in 2018, a decrease from $40 \%$ in 2017. Almost all the Russian catch in 2018 was taken in Division 2.a. The wide geographical distribution of the fishery noted in previous years has continued.

The time series of catches by country from the North Sea, Skagerrak and Kattegat (Subarea 4, Division 3.a) is given in Table 8.4.2.2. Catches in 2018 amounted to 342147 t , an increase of 72343 t from 2017. The majority of the catch is from Subarea 4 with small catches were also reported in Divisions 3.a-d.

Catches in the western area (Subareas 6, 7 and Divisions 8.a,b,d and e) decreased slightly to 194180 t with most of the traditional fishing nations catching less mackerel in 2018 than 2017 The catches are detailed in Table 8.4.2.3.

Table 8.4.2.4 details the catches in the southern areas (Divisions 8.c and 9.a) which are taken almost exclusively by Spain and Portugal. The reported catch of 34369 t represents an increase from 2017. The catch is close to the long-term average.

The distribution of catches by quarter (\%) is described in the text table below:

| Year | Q1 | Q2 | Q3 | Q4 | Year | Q1 | Q2 | Q3 | Q4 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1990 | 28 | 6 | 26 | 40 | 2005 | 46 | 6 | 25 | 23 |
| 1991 | 38 | 5 | 25 | 32 | 2006 | 41 | 5 | 18 | 36 |
| 1992 | 34 | 5 | 24 | 37 | 2007 | 34 | 5 | 21 | 40 |
| 1993 | 29 | 7 | 25 | 39 | 2008 | 34 | 4 | 35 | 27 |
| 1994 | 32 | 6 | 28 | 34 | 2009 | 38 | 11 | 31 | 20 |
| 1995 | 37 | 8 | 27 | 28 | 2010 | 26 | 5 | 54 | 15 |
| 1996 | 37 | 8 | 32 | 23 | 2011 | 22 | 7 | 54 | 17 |
| 1997 | 34 | 11 | 33 | 22 | 2012 | 22 | 6 | 48 | 24 |
| 1998 | 38 | 12 | 24 | 27 | 2013 | 19 | 5 | 52 | 24 |
| 1999 | 36 | 9 | 28 | 27 | 2014 | 20 | 4 | 46 | 30 |
| 2000 | 41 | 4 | 21 | 33 | 2015 | 20 | 5 | 44 | 31 |
| 2001 | 40 | 6 | 23 | 30 | 2016 | 23 | 4 | 44 | 29 |
| 2002 | 37 | 5 | 29 | 28 | 2017 | 24 | 3 | 45 | 28 |
| 2003 | 36 | 5 | 22 | 37 | 2018 | 20 | 3 | 40 | 37 |
| 2004 | 37 | 6 | 28 | 29 |  |  |  |  |  |

The quarterly distribution of catch in 2018 is similar to recent years (since 2010) with the northern summer fishery in Q3 accounting for the greatest proportion of the total catch.
Catches per ICES statistical rectangle are shown in Figures 8.4.2.1 to 8.4.2.4. It should be noted that these figures are a combination of official catches and ICES estimates and may not indicate the true location of the catches or represent the location of the entire stock. These data are based on catches reported by all the major catching nations and represents almost the entire ICES estimated catch.

- $\quad$ First quarter 2018 (200 408 t-20\%)

The distribution of catches in the first quarter is shown in Figure 8.4.2.1. The quarter 1 fishery is similar to that in previous years with the Scottish and Irish pelagic fleets targeting mackerel in Divisions 6.a, 7.b and 7.j. Substantial catches are also taken by the Dutch owned freezer trawler fleet. The largest catches were taken in Division 6.a, as in recent years. The Spanish fisheries also take significant catches along the north coast of Spain during the first quarter.

- $\quad$ Second quarter 2018 (34 $125 \mathrm{t}-3 \%$ )

The distribution of catches in the second quarter is shown in Figure 8.4.2.2. The quarter 2 fishery is traditionally the smallest and this was also the case in 2018. The most significant catches where those in Division 8.c and at the start of the summer fishery in northern waters by Icelandic, Norwegian and Russian fleets.

- Third quarter 2017 (412 146 t - 40\%)

Figure 8.4.2.3 shows the distribution of the quarter 3 catches. Large catches were taken throughout Divisions 2.a (Russian, Norwegian vessels), 4.a (Norwegian, Scottish vessels), 5.a (Icelandic vessels). Catch was also taken in Division 14.b in quarter 3.

- Fourth quarter 2017 (379 758 t-37\%)

The fourth quarter distribution of catches is shown in Figure 8.4.2.4. The summer fishery in northern waters has largely finished although there are substantial catches reported in the southern part of Division 2.a. The largest catches are taken by Norway, Scotland and Ireland around the Shetland Isles and along the north coast of Scotland. The pattern of catches is very similar to that reported in recent years.

ICES cannot split the reported mackerel catches into different stock components because there is no clear distinction between components upon which a split could be determined. Mackerel with a preference for spawning in the northeast area, including the North Sea, cannot presently be identified morphometrically or genetically (Jansen and Gislason, 2013). Separation based on time and area of the catch is not a precise way of splitting mackerel with different spawning preferences, because of the mixing and migration dynamics including inter-annual (and possibly seasonal) variation of the spawning location, combined with the post-spawning immigration of mackerel from the south-west where spawning ends earlier than in the North Sea.

### 8.4.3 Catch-at-Age

The 2018 catches in number-at-age by quarter and ICES area are given in Table 8.4.3.1. This catch in numbers relates to a total ICES estimated catch of 1026437 t . These figures have been appended to the catch-at-age assessment table (see Table 8.7.1.2).

Age distributions of commercial catch were provided by Denmark, England, Germany, Faroes, Iceland, Ireland, the Netherlands, Norway, Portugal, Russia, Scotland and Spain. There remain gaps in the age sampling of catches, notably from France (length samples were provided), Sweden, Poland and Greenland.

Catches for which there were no sampling data were converted into numbers-at-age using data from the most appropriate fleets. Accurate national fleet descriptions are required for the allocation of sample data to unsampled catches.
The percentage catch numbers-at-age by quarter and area are given in Table 8.4.3.2.
As in previous years almost $80 \%$ of the catch in numbers in 2018 consists of 3 to 8 -year olds with all year classes between 2010 and 2014 contributing over $10 \%$ to the total catch by number.
There is a small presence of juvenile (age 0) fish within the 2018 catch. As in previous years catches from Divisions 8.c and 9.a have contained a proportion of juveniles.

### 8.5 Biological Data

### 8.5.1 Length Composition of Catch

The mean lengths-at-age in the catch per quarter and area for 2018 are given in Table 8.5.1.1.
For the most common ages which are well sampled there is little difference to recent years. The length of juveniles is traditionally rather variable. The range of lengths recorded in 2018 for 0 group mackerel ( $162 \mathrm{~mm}-254 \mathrm{~mm}$ ) are higher than those in 2017 ( $131 \mathrm{~mm}-212 \mathrm{~mm}$ ). The rapid growth of 0-group fish combined with variations in sampling (in recent years more juvenile fish
have been sampled in northern waters whereas previously these fish were only caught in southern waters) will contribute to the observed variability in the observed size of 0-group fish. Growth is also affected by fish density as indicated by a recent study which demonstrated a link between growth of juveniles and adults ( $0-4$ years) and the abundance of juveniles and adults (Jansen and Burns, 2015). A similar result was obtained for mature 3- to 8-year-old mackerel where a study over 1988-2014 showed declining growth rate since the mid-2000s to 2014, which was negatively related to both mackerel stock size and the stock size of Norwegian spring spawning herring (Ólafsdóttir et al., 2015).

Length distributions of the 2018 catches were provided by England, Faroes, France, Iceland, Ireland, Germany, Greenland, the Netherlands, Portugal, Russia, Scotland and Spain. The length distributions were available from most of the fishing fleets and account for over $90 \%$ of the catches. These distributions are only intended to give an indication of the size of mackerel caught by the various fleets and are used as an aid in allocating sample information to unsampled catches. Length distributions by country and fleet for 2018 catches are given in Table 8.5.1.2.

### 8.5.2 Weights at Age in the Catch and Stock

The mean weights-at-age in the catch per quarter and area for 2018 are given in Table 8.5.2.1. There is a trend towards lighter weights-at-age for the most age classes (except 0 to 2 years old) starting around 2005 is continuing until 2013 (Figure 8.5.2.1). This decrease in the catch mean weights-at-age seems to have stopped since 2013 and values for the last five years do not show any particular trend for the older ages (age 6 and older) and are slightly increasing for younger ages (ages 1 to 5). These variations in weight-at-age are consistent with the changes noted in length in Section 8. 5.1.

The Working Group used weights-at-age in the stock calculated as the average of the weights-at-age in the three spawning components, weighted by the relative size of each component (as estimated by the 2019 egg survey for the southern and western components and the 2017 egg survey for the North Sea component). Mean weights-at-age in 2018 for the western component are estimated from Dutch, Irish and German commercial catch data, the biological sampling data taken during the egg surveys and during the Norwegian tagging survey. Only samples corresponding to mature fish, coming from areas and periods corresponding to spawning, as defined at the 2014 benchmark assessment (ICES, 2014) and laid out in the Stock Annex, were used to compute the mean weights-at-age in the western spawning component. For the North Sea spawning component, mean weights-at-age in 2018 were calculated from samples of the commercial catches collected from Divisions 4.a and 4.b in the second quarter of 2017. Stock weights for the southern component, are based on samples from the Portuguese and Spanish catch taken in Divisions 8.c and 9.a in the $2^{\text {nd }}$ quarter of the year. The mean weights in the three components and in the stock in 2018 are shown in the text table below.

As for the catch weights, the decreasing trend observed since 2005 for fish of age 3 and older seems to have stopped in 2013 and values in the last four years do not show any specific trend (except for weights of ages 2 to 5 which have been increasing, Figure 8.5.2.2).

|  | North Sea Component | Western <br> Component | Southern Component | NEA Mackerel $2017$ |
| :---: | :---: | :---: | :---: | :---: |
| Age |  |  |  | Weighted mean |
| 0 |  |  |  | 0.000 |
| 1 |  |  | 0.085 | 0.063 |
| 2 | 0.200 | 0.206 | 0.142 | 0.191 |
| 3 | 0.303 | 0.253 | 0.291 | 0.266 |
| 4 | 0.294 | 0.281 | 0.285 | 0.283 |
| 5 | 0.328 | 0.308 | 0.326 | 0.314 |
| 6 | 0.352 | 0.322 | 0.334 | 0.327 |
| 7 | 0.366 | 0.343 | 0.347 | 0.346 |
| 8 | 0.395 | 0.363 | 0.356 | 0.364 |
| 9 | 0.389 | 0.392 | 0.379 | 0.389 |
| 10 | 0.447 | 0.419 | 0.409 | 0.419 |
| 11 | 0.441 | 0.448 | 0.403 | 0.437 |
| 12+ | 0.465 | 0.490 | 0.490 | 0.488 |
| Component Weighting | 8.5\% | 68.1\% | 23.4\% |  |
| Number of fish sampled | 98 | 658 | 736 |  |

### 8.5.3 Natural Mortality and Maturity Ogive

Natural mortality is assumed to be 0.15 for all age groups and constant over time.
The maturity ogive for 2018 was calculated as the average of the ogives of the three spawning components weighted by the relative size of each component calculated as described above for the stock weights. The ogives for the North Sea and Southern components are fixed over time. For the Western component the ogive is updated every year, using maturity data from commercial catch samples collected during the first and second quarters (ICES, 2014 and Stock Annex). The 2018 maturity ogives for the three components and for the mackerel stock are shown in the text table below.

A trend towards earlier maturation (increasing proportion mature at age 2) has been observed from the around 2008 to 2015 . A change in the opposite direction has been observed since then and the proportion of fish mature at age in 2018 are now markedly lower that in the previous years, at levels comparable with the one observed at the end of the 2000s (Figure 8.5.3.1).

| Age | North Sea | Western Component | Southern Component | NEA Mackerel |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | 0 |
| 1 | 0 | 0.12 | 0.02 | 0.09 |
| 2 | 0.37 | 0.44 | 0.54 | 0.46 |
| 3 | 1 | 0.92 | 0.70 | 0.88 |
| 4 | 1 | 1 | 1 | 1 |
| 5 | 1 | 1 | 1 | 1 |
| 6 | 1 | 1 | 1 | 1 |
| 7 | 1 | 1 | 1 | 1 |
| 8 | 1 | 1 | 1 | 1 |
| 10 | 1 | 1 | 1 | 1 |
| 11 | 1 | 1 | 1 | 1 |
| $12+$ | 1 | $23.4 \%$ | 1 |  |
| Component Weighting | $8.5 \%$ | 1 | $1 \%$ | 1 |

### 8.6 Fishery Independent Data

### 8.6.1 International Mackerel Egg Survey

The ICES Triennial Mackerel and Horse Mackerel Egg Survey for 2019 was carried out during January - August. Final results will be presented at the WGMEGS meeting in April 2020. The results have been used in the assessment for mackerel since 1977. Since 2004 and subsequent to demands for up-to-date data for the assessment, WGMEGS aims to provide a preliminary estimate of NEA mackerel biomass and western horse mackerel egg production in time for the assessment meetings within the same calendar year as the survey.

WGMEGS presents the preliminary results of the 2019 mackerel and horse mackerel egg survey provided for WGWIDE in August 2019. The final survey results will be available during the next WGMEGS meeting in April 2020. This is due to the extremely large numbers of plankton and fecundity samples to be analysed following the surveys as well as the tight deadline set by WGWIDE for delivering these estimates. A working document ( $\mathrm{O}^{\prime}$ Hea et al., 2019) with the preliminary results of the survey was presented to WGWIDE members on time.

The 2019 survey plan was split into 6 sampling periods. Maximum deployment of effort in the Western area was during periods three, four, five and six (ICES, 2018c). Historically these periods would have coincided with the expected peak spawning of both mackerel and horse mackerel. In recent years mackerel peak spawning has been taken place during periods 3 and 5 . Due to the expansion of the spawning area which has been observed since 2007, the emphasis was even more focused on full area coverage and delineation of the spawning boundaries.

Analyses of the plankton and fecundity samples were carried out according to the sampling protocols as described in the ICES Survey Protocols SISP 5 and SISP 6 (ICES, 2019b, ICES, 2019c).

### 8.6.1.1 Data analysis for mackerel annual egg production

Egg counts were converted to stage 1 egg production, using data on the volume of water filtered. These values were then converted to egg production/day $/ \mathrm{m}^{2}$ using the development equations and water temperature at 20 m depth. Arithmetic means were used where more than one sample per rectangle per period was collected. Daily egg production values were interpolated into un-
sampled rectangles according to procedures described in the above report. Plots of the distribution of egg production for the western area are presented in Figures 8.6.1.1-8.6.1.6. Interpolated values are highlighted in red. The area coverage is described in detail in the working document from O' Hea et al. (2019) presented to WGWIDE.

Figure 8.6.1.7 presents the egg production curve for the western area for the 2019 survey, along with those for the previous surveys for comparison. 2010 provided an unusually large spawning event early in the spawning season, 2013 yielded an even larger spawning event indicating that spawning was probably taking place well before the nominal start date of $10^{\text {th }}$ February (day 42). In 2016 the first survey commenced on February 5th which is five days prior to the nominal start date. The pattern in 2019 followed that of 2016 with no early peak spawning being recorded. This year however, peak spawning was found to have taken place in period 4, rather than period 5 as the case in 2016. Unlike 2016 when concern was expressed that survey coverage may have underestimated the total egg production estimate, area coverage in 2019 was much better. The expansion observed in western and north-western areas during periods 5 and 6 in 2016 was once again reported during 2019. However, egg numbers were not as large as in 2016 (Figures 8.6.1.45). During these periods it was not possible to fully delineate the northern and north-western boundaries. However, an analysis provided significant evidence that while some spawning has been missed the loss of egg abundance is not sufficiently large to significantly impact the SSB estimate.
The nominal end of spawning date of the $31^{\text {st }} \mathrm{July}$ is the same as was used during previous survey years and the shape of the egg production curve for 2019 does not suggest that the chosen end date needs to be altered. The provisional total annual egg production (TAEP) for the western area in 2019 was calculated as $1.22 * 10^{15}$. This is a $20 \%$ reduction on the 2016 TAEP estimate which was $1.55 * 10^{15}$.
Figure 8.6.1.8 shows the egg production curve for the southern area for the 2019 survey, along with those for previous surveys for comparison. The start date for spawning in the southern area was the 23rd January). The Portuguese period 1 survey in division 9.a was pushed back by around 1 week. The result being that the survey dates aligned more closely to period 2 . It was subsequently re-classified within period 2 and survey period 1 was removed. Sampling in the Cantabrian Sea, where the majority of spawning occurs within the Southern area, commenced 6 days later than in 2016 on the $14^{\text {th }}$ March. The same end of spawning date of the $17^{\text {th }}$ July was used again this year and the spawning curve suggests that there is no reason for this to change. As in 2016 the survey periods were not completely contiguous, and this has been accounted for. The provisional total annual egg production (TAEP) for the southern area in 2019 was calculated as $4.19{ }^{*} 10^{14}$. This is a $54 \%$ increase on the 2016 TAEP estimate which was $2.25 * 10^{14}$.

A comparison of the total annual egg production (TAEP) for the western and southern area over the last survey years is given below:

| Year | Western TAEP | Southern TAEP |
| :--- | :--- | :--- |
| 2019 | $1.22 * 10^{15}$ | $4.19 * 10^{14}$ |
| 2016 | $1.55 * 10^{15}$ | $2.25 * 10^{14}$ |
| 2013 | $1.20 * 10^{15}$ | $5.06 * 10^{14}$ |
| 2010 | $1.42 * 10^{15}$ | $4.59 * 10^{14}$ |
| 2007 | $1.36 * 10^{15}$ | $3.48 * 10^{14}$ |
| 2004 | $1.35 * 10^{15}$ | $3.18 * 10^{14}$ |
| 2001 | $1.54 * 10^{15}$ | $4.79 * 10^{14}$ |
| 1998 |  |  |

Total annual eggs production (TAEP) for both the western and southern components combined in 2019 is $1.63{ }^{*} 10^{15}$. This is a decrease in production of $9 \%$ compared to 2016 (Figure 8.6.1.9).

### 8.6.1.2 Mackerel fecundity and atresia estimation

Estimates of fecundity are given as preliminary realised fecundity which is the potential fecundity minus the atresia rate (for details see O' Hea et al., 2019). The analysis of potential fecundity is carried out by four different participating institutes. Preliminary results are based on a limited number (34) of samples from period 2 and 3 . This number of samples have been lower than in 2016, when 66 samples were available for the preliminary potential fecundity. The preliminary relative potential fecundity in 2019 is 1224 oocytes/gram female slightly higher than preliminary estimate in 2016 ( 1215 oocytes/gram female). Due to time constraints no samples were analysed for atresia at the time of WGWIDE. For the preliminary estimation of the realised fecundity the mean atresia rate based on the last six survey years (6\%) was used. This resulted in a preliminary realised fecundity estimate for 2019 of 1142 oocytes/gram female fish.

### 8.6.1.3 Quality and reliability of the 2019 egg survey

The 2019 survey shows a good spatial and temporal coverage in each of the sampling periods.
The previous surveys in 2010 and 2013 have been dominated by the issue of early peak of western mackerel spawning and its close proximity to the nominal start date. Both the 2013 and 2016 surveys were determined to address this issue with the result that sampling in the western area during these years commenced 2 weeks earlier than the preceding survey in an effort to capture the start of spawning. The pattern in 2019 followed that of 2016 with no early peak spawning being recorded. This year, however, peak spawning for western component was found to have taken place in period 4 which in regard to its temporal position has been early that of 2016 (Figure 8.6.1.7). The bulk of the spawning activity reported during historical surveys resulted from several egg production hotspots on and around the continental shelf edge and usually around the Celtic Sea and Porcupine Bank region. During 2019, high levels of egg production were recorded close to the 200 m contour line in Cantabrian Sea, Bay of Biscay, Porcupine Bank and from Cape Wrath to Shetland. (Figures 8.6.1.2-8.6.1.5). As it was noted in 2016, a low to moderate egg production at westwards and northwards of North of $54^{\circ} \mathrm{N}$ was found. Although it was not possible to fully delineate the boundary in this region during periods 5 and 6 . It was accepted that this north and north-westerly unaccounted egg production would contribute only a small proportion
of the TAEP in the western area. WGMEGS is confident that this survey accurately reflects the spawning patterns and that the survey has been successful in capturing the bulk of spawning activity. Further analysis of the quality and reliability of the survey will be done by WGMEGS in April 2020.

### 8.6.1.4 Mackerel biomass estimates

Based on the total annual egg production (TAEP) for the western and southern component, a preliminary realized fecundity estimate of 1142 oocytes/gr female, a sex ratio of 1:1 and a raising factor of 1.08 , the preliminary total spawning stock biomass (SSB) was estimated as shown below:

$$
S S B=\frac{T A E P}{F^{\prime}} * s * c f
$$

Where
$F^{\prime}=$ realized fecundity,
$s=2$ for a given sex ratio of 1:1,
$\mathrm{cf}=1.08$ (fixed raising factor to convert pre-spawning to spawning fish)

Giving

- $\quad 2.301$ million tonnes for western component (2016: 3.077).
- 0.792 million tonnes for southern component (2016: 0.447).
- 3.092 million tonnes for western and southern components combined (2016:3.524)

### 8.6.2 Demersal trawl surveys in October - March (IBTS Q4 and Q1)

## The data and the model

An index of survivors in the first autumn-winter (recruitment index) was derived from a geostatistical model fitted to catch data from bottom trawl surveys conducted during autumn and winter. A complete description of the data and model can be found in Jansen et al. (2015) and the NEA mackerel Stock Annex.

The data were compiled from several bottom trawl surveys conducted between October and March from 1998-2019 by research institutes in (Denmark, England, France, Germany, Ireland, Netherlands, Norway, Scotland and Sweden). Surveys conducted on the European shelf in the first and fourth quarters are collectively known as the International Bottom Trawl Survey (IBTS), although several of the surveys use different names. All surveys sample the fish community on the continental shelf and upper shelf slope. IBTS Q4 covers the shelf from the Bay of Biscay to North of Scotland, excluding the North Sea, while IBTS Q1 covers the shelf waters from north of Ireland, around Scotland, the North Sea, Skagerrak and Kattegat.

Trawl operations during the IBTS have largely been standardized through the relevant ICES working group (ICES, 2013b). Furthermore, the effects of variation in wing-spread and trawl speed were included in the model (Jansen et al., 2015). Trawling speed was generally 3.5-4.0 knots, and trawl gear is also standardized and collectively known as the Grande Ouverture Verticale (GOV) trawl. Some countries use modified trawl gear to suit the particular conditions in the respective survey areas, although this was not expected to change catchability significantly. However, in other cases, the trawl design deviated more significantly from the standard GOV
type, namely the Spanish BAKA trawl, the French GOV trawl, and the Irish mini-GOV trawl. The BAKA trawl had a vertical opening of only $2.1-2.2 \mathrm{~m}$ and was towed at only 3 knots. This was considered substantially less suitable for catching juvenile mackerel and, therefore, was excluded from the analysis. The French GOV trawl was rigged without a kite and typically had a reduced vertical opening, which may have reduced the catchability of pelagic species like mackerel. Catchability was assumed to equal the catchability of the standard GOV trawl because testing has shown that the recruitment index was not very sensitive to this assumption (Jansen et al., 2015). Finally, the Irish mini-GOV trawl, used during 1998-2002, was a GOV trawl in reduced dimensions which was accounted for by inclusion of the wing-spread parameter in the model.
All surveys in 2018 Q4 and 2019 Q1 were conducted according to standards. Figure 8.6.2.1 provides an overview of the distribution and number of samples.

A geostatistical log-Gaussian Cox process model (LGC) with spatiotemporal correlations was used to estimate the catch rates of mackerel recruits through space and time.

## Results

The index of survivors in the first autumn-winter (recruitment index) was updated with data from surveys in 2018 Q4 and 2019 Q1. Parameter estimates and standard errors in the final model are listed in Table 8.6.2.1. The modelled average recruitment index (squared CPUE) surfaces were mapped in Figure 8.6.2.2. The timeseries of spatially integrated recruitment index values is used in the assessment as a relative abundance index of mackerel at age 0 (recruits). All annual index values were estimated to be slightly higher than during the previous model fit in IBPNEAMac (ICES, 2019a), but with the same interannual pattern ( $p<0.001, r=0.9986$ ). This increase does not affect the stock assessment because it is used in the assessment as a relative abundance index. The estimated index value for the 2018 year class is above average (Figure 8.6.2.3).

## Discussion

The combined demersal surveys have incomplete spatial coverage in some areas that can be important for the estimation of age-0 mackerel abundance, namely: (i) Since 2011, the English survey (covering the Irish sea and the central-eastern part of the Celtic sea including the area around Cornwall) has been discontinued; (ii) the Scottish survey has not consistently covered the area around Donegal Bay; and (iii) the IBTS has observed high catch rates in some years at the northeastern edge of the survey area (towards the Norwegian trench) in winter. It is therefore possible that some recruits are also overwintering on the other side of the trench along the south western shelf edge of Norway. Consequently, the NS-IBTS in Q1 should be extended to include the southwestern Norwegian shelf and shelf edge in proximity to the Norwegian trench.

Finally, WGWIDE encourage studies of vertical distribution and catchability of age- 0 mackerel in the Q4 and Q1 surveys, to evaluate if it is comparable in all areas (see acoustic information in Jansen et al., 2015).

### 8.6.3 Ecosystem surveys in the Nordic Seas in July-August (IESSNS)

The IESSNS was successfully conducted in the summer of 2019 (Figure 8.6.3.1). Six vessels sampled 309 predetermined surface trawl stations during the period from June 28 to August 5 which covered an area of 3.2 mill. $\mathrm{km}^{2}, 2.9$ mill. $\mathrm{km}^{2}$ excluding the North Sea, which was similar coverage to 2018 (Nøttestad et al., 2019). At each surface trawl station, a standardized trawl (Multpelt 832 ) is employed for $30-\mathrm{min}$ according to a standardize operation protocol which is designed to catch mackerel. Additionally, abundance of herring and blue whiting was measured using
acoustic methods, excluding the North Sea, and backscatter was verified by trawling on registrations as needed. The aim is to establish an index for blue whiting and herring abundance to be used in stock assessment in the future. The IESSNS 2019 cruise report is available as a working document to the current report (Nøttestad et al., 2019) and a detailed survey description is in the mackerel Stock Annex.

IESSNS provides an annual age-segregated index for mackerel abundance for age classes 1-14+ in Nordic Seas since 2010 and in the North Sea since 2018 (ICES, 2019a). In the current chapter, the North Sea mackerel data are reported separately from longer time series available from the Nordic Sea area. In Nordic Seas, total stock abundance (numbers) was estimated 26.4 billion and biomass was estimated 11.5 million tons which is compared to 2018 an increase of $56 \%$ and $85 \%$, respectively (Table 8.6.3.1 and Figure 8.6.3.2a). Estimate stock abundance (billions) in 2019 is the second highest for the timeseries (Figure 8.6.3.2b), and in similar range as estimates for the period from 2013 to 2017 (Nøttestad et al., 2019). Catch curve analysis of cohort numbers for the period from 2010 to 2019 displays "a dip" for all age classes in 2018 (Figure 8.6.3.3), indicating annual effects in the survey (Nøttestad et al., 2019).

The most abundant year classes were 2011, 2010 and 2016 respectively presenting $14.8 \%, 14.5 \%$ and $14.4 \%$ of the total stock in numbers (Figure 8.6.3.4a, b). These cohorts were also abundant in 2018. Internal consistency of year classes is highly variable with correlation values ranging from 0.13 to 0.93 (Figure 8.6.3.5). There was a significant ( $\mathrm{p}<0.05$ ) internal consistency for ages 1 to 5 years ( $0.83<\mathrm{r}<0.93$ ), it was not significant but fairly good for ages 6 to 7 and for ages 8 to 12 $(0.58<r<0.81)$, and it was poor between ages 5 and $6(r=0.31)$ and ages 7 and $8(r=0.13)$ (Figure 8.6.3.5). Compared to 2018, internal consistency was similar for most ages except there was a noticeable decline for ages 5-6 and ages 7-8. It is worth noting that the internal consistency plots have seven data points each, hence one data point can have large influence on the correlation.

Mackerel density, per predetermined surface trawl station, ranged from 0 to 52 tonnes $/ \mathrm{km}^{2}$ with the highest densities recorded in the northern Norwegian Sea, south-east of Iceland, between Iceland and the Faroe Island, as well as south west of the Faroe Islands (Nøttestad et al., 2019) Mackerel geographical distribution began shifting eastward in 2018 compared to the period from 2010 to 2017 (Figure 8.6.3.6b). This eastward distributional shift continued in 2019 with limited amount of mackerel caught westward of longitude $27^{\circ} \mathrm{W}$ (Figure 8.6.3.6a) (Nøttestad et al., 2019). For comparison, the westward boundary of mackerel was at longitude $43^{\circ} \mathrm{W}$ in 2014 which is the year with the largest geographical distribution range.

For age classes 3-11, which are included in stock assessment (ICES, 2019a), increased in numbers was $98 \%$ compared to $56 \%$ for all age classes. This discrepancy is caused by age classes 1 and 2 being $70 \%$ lower in 2019 compared to 2018. The record high numbers of age 1 in 2018 resulted in below medium number at age 2 in 2019, and age 1 numbers in 2019 were among the lowest recorded (Figure 8.6.3.4a). The IESSNS is considered not cover the complete distribution range of youngest two-year classes, hence they are excluded from the assessment. However, the internal consistency between ages 1-3 suggests abundance at ages 1 and 2 gives an indication of year class size prior to recruitment into the survey at age 3 (Figure 8.6.3.5).

The North Sea (southward of latitude $60^{\circ} \mathrm{N}$ ) was included in the IESSNS for the second time in July 2019 with 38 predetermined surface trawl stations were sampled and survey area covering 0.28 mill. $\mathrm{km}^{2}$ (Figure 8.6.3.6a). The mackerel abundance index was 1.0 billion and the biomass index was 0.2 million ton which was a decrease of $53 \%$ and $42 \%$ compared to 2018, respectively (Figure 8.6.3.6b) (Nøttestad et al., 2019).

### 8.6.4 Tag Recapture data

## Steel-tags

The Institute of Marine Research in Bergen (IMR) has conducted tagging experiments on mackerel on annual basis since 1968, both in the North Sea and to the west of Ireland during the spawning season May-June. Information from steel-tagged mackerel tagged west of Ireland and British Isles was introduced in the mackerel assessment during ICES WKPELA 2014 (ICES, 2014), and data from release years 1980-2004, and recapture years 1986-2006 has been used in the update assessments after this. The steel tag experiments continued to 2009, with recaptures to 2010, but this part of the data was at the time considered less representative and was excluded.

What is used in the SAM stock assessment is a table of data showing numbers of steel tagged fish per year class in each release year, and the corresponding numbers scanned and recaptured of the same year classes in all years after release. The steel tag data and the corresponding trends in the data in terms of index of total biomass and year class abundance by year is described in (Tenningen et al., 2011).

The steel tag methodology involved a whole lot of manual processes, demanding a lot of effort and reducing the possibility to scan larger proportions of the landings. The tags were recovered at metal detector/deflector gate systems installed at plants processing mackerel for human consumption. This system demanded external personnel to stay at the plants supervising the systems during processing. Among the typical 50 fish deflected, the hired personnel had to find the tagged fish with a hand-hold detector and send the fish to IMR for further analysis. It was decided in the end to go for a change in methodology to radio-frequency identification (RFID), which would allow for more automatic processes and increased proportion of scanned landings.

## RFID tags

The RFID tagging project on NEA mackerel was initiated in 2011 by IMR, and the data was used in update assessments after the ICES WKWIDE2017 benchmark meeting (ICES, 2017b). The data format was the same as for steel tags, but the time series were treated with a different scaling parameter in the assessment.
RFID is a technology that uses radio waves to transfer data from an electronic tag, called an RFID tag, through a reader for the purpose of identifying and tracking the object. The tag itself is passive but information to the reader is released as it passes an electric field in the antenna system, and information is automatically updated in an IMR database. When tagging and releasing the fish, information is also synced to the IMR database regularly over internet.

There is a web-based software solution and database that is used to track the different scanning systems at the factories, import data on catch information, and biological sampling data of released fish and screened catches. Based on this information the system can estimate numbers released every year, and the concurrent numbers screened and recaptured over the next years (by year class). The development of the tagging data time series is dependent on the work from each country's research institutes, fisheries authorities or the industry it selves to provide additional data about catches screened through the RFID systems, such as total catch weight, position of catch (ICES rectangle), mean weight in catch, etc. Regular biological sampling of the catches landed at these factories is also needed. Altogether, these data are essential for the estimation of numbers screened per year class. Responsible scientists in Norway, Iceland, Faroes and Scotland has been following up the factories, and delivering the catch data and biological data. In the future it is planned that annual workshops should occur prior to the assessment, where more
scientists go through the new data being updated from new tagging experiments, as well as recaptures from all previous experiments, undertake quality assurance of the data and other analyses of the trends in the data outside of the assessment model.

The RFID tagging technology is clearly a more cost-effective than the old steel tag technology. We are now scanning about 10 times more biomass than during the period with steel tags. An overview of the RFID tagging data in terms of numbers tagged, biomass scanned, and numbers recaptured is given in Tables 8.6.4.1-3, and geographical distributions of data in Figure 8.6.4.1.

During the period 2011 - 1th September 2019 as many as 408325 mackerel have been tagged with RFID (Table 8.6.4.1). This includes an experiment off the Norwegian Coast on young mackerel in September 2011 as well as five experiments carried out in August in Iceland 2015-2019, none of which are included as input data in the assessment. Data from the releases at the spawning grounds in May-June of Ireland and the Hebrides are the only data included in the assessment.

The 4490 RFID-tagged mackerel recaptured up to 1th September 2019 came from 23 European factories processing mackerel for human consumption (Table 8.6.4.3). The project started with RFID antenna reader systems connected to conveyor belt systems at 8 Norwegian factories in 2012. Now there are 6 operational systems at 5 factories in UK (Denholm has 2 RFID systems) and 3 in Iceland. Norway has installed RFID systems at 8 more factories in 2017-2018, most of which with the purpose of scanning Norwegian spring spawning herring catches (IMR started tagging herring in 2016), but some also processing mackerel. More systems are also bought by Ireland (3), which up to now has been non-operational. The working document from Slotte (2019) presented to WGWIDE, describes potential problems with some of the factories that has led to the exclusion of the data for use in assessment, the data from factories used in the 2019 assessment is marked in Tables 8.6.4.2-3.

During ICES WGWIDE 2018 (ICES, 2018d) meeting bias issues were described for RFID tag data, in addition to potential weighting issues of the tag data inside the model. After the intermediate benchmark meeting ICES IBPNEAMac 2019 (ICES, 2019a), these issues were overcome by using a subset of data for release years (exclude 2011-2012), recapture years (only use recaptures from year 1 and 2 after release) and age groups (exclude youngest fish ages $2-4$, use ages 5-11). This is now the subset of data to be used in update assessments, and it is illustrated in Tables 8.6.4.1-3 where subset data currently used are marked.

Figure 8.6.4.2 shows the relative distributions of year classes tagged per year and scanned/recaptured year 1 and 2 after release for the subset years used in current update assessment. The figure illustrates the problem that the tagged/recaptured fish are skewed towards older fish than scanned. Especially the large year classes 2010-2011 were tagged in low numbers at ages 2-4 compared with the scanned numbers. However, for the latest release used in the assessment (2017), it seems that this tendency is less pronounced.

During ICES WGWIDE 2018 (ICES, 2018d) the RFID tag data had high weight, and the SSB trend in the assessment showed a clear tendency to decrease from 2011-2016. This was also consistent with the observed trend in the data from various abundance index data from the RFID tag-recapture time series explored during ICES IBPNEAMac 2019 (ICES, 2019a). However, by using the current subset data this changed the trend in the RFID tag data significantly, which is demonstrated by comparing the index of abundance from RFID data using all data and the subset data (Figure 8.6.4.3). Here it is also obvious that adding one more year of release and recapture data results in increases abundance in release years 2011-2012, as well as a very clear downward trend to 2017. On the other hand, adding one more release year and recapture year in the subset data lifts the index in 2016 to same level as in 2017. The subset data indicate a weak increase in abundance from 2013-2017, rather than a decrease.

Estimates of year class abundance for the subset of RFID tag-recapture data used in the current assessment also show differences in year class levels and trends over time that seems reasonable with no clear year effects, and with a year class development following a total mortality of approximately $\mathrm{Z}=0.4$ (Figure 8.6.4.4). These estimates of year class trends and trends in aggregated abundance over ages should be continued to be explored in next update assessments, as this is format that is easier to evaluate than the actual raw data used in the SAM model.

### 8.6.5 Other surveys

### 8.6.5.1 International Ecosystem survey in the Norwegian Sea (IESNS)

After the mid-2000s an increasing amount of NEA mackerel has been observed in catches in the Norwegian Sea during the combined survey in May during the International Ecosystem survey in the Norwegian Sea (IESNS) targeting herring and blue whiting (Rybakov et al., 2016; 2017). The spatial distribution pattern of mackerel was reduced in 2019 compared to 2017 and 2018 (Rybakov et al., 2017; ICES, 2018b; Salthaug et al., 2019). Mackerel was caught within a more limited area and in fewer trawl stations of the Norwegian Sea in May 2019 compared to May 2017 and 2018 (Rybakov et al., 2017; ICES, 2018b; Salthaug et al., 2019). In 2019, the northernmost mackerel catch was at $66^{\circ} \mathrm{N}$ and the westernmost catch was at $2^{\circ} \mathrm{W}$, whereas in 2018, the northernmost mackerel catch was at $70^{\circ} \mathrm{N}$ and the westernmost catch was similar at $2^{\circ} \mathrm{W}$. Mackerel of age 3 dominated followed by age 5 in 2019, whereas there was found much less 1 -year olds compared to last year (Salthaug et al., 2019).

The IESNS survey provide valuable although limited quantitative information can be drawn. This acoustic based survey is not designed to monitor mackerel, and do not provide proper mackerel sampling in the vertical dimension and involve too low trawl speed for representative sampling of all size groups of mackerel. The trawl hauls are mainly targeting acoustical registrations of herring and blue whiting during the survey in May (IESNS) (Salthaug et al., 2019).

### 8.6.5.2 Acoustic estimates of mackerel in the Iberian Peninsula and Bay of Biscay (PELACUS)

The northern Spanish waters (8.c and 9.a.N) were surveyed in PELACUS 0319 on board RV Miguel Oliver from $27^{\text {th }}$ March till $19^{\text {th }}$ April, using the methodology of the previous surveys.
The bulk of the mackerel distribution, as in previous years, was located just in the middle of the Cantabrian Sea (Cape Peñas), extending throughout the surveyed area (Figure 8.6.5.2.1). A total of 905 thousand tonnes, corresponding to 2549 million fish were estimated, which represent an important increase from the 2018 estimates ( 557 thousand tonnes). Bigger fish (mainly age group 7) occurred in the westernmost part, while age group 5 in the rest of the area. (Figure 8.6.5.2.2, Tables 8.6.5.2.12).

Although biomass was higher, spawning area was lower than the one derived last year (246 positive egg stations of 367 this year; 364 of 373 in 2018), but probably due to the increase of the adult abundance, egg density was higher than that calculated last year (mean of 397 eggs per stations, corresponding to $36.21 \mathrm{eggs} / \mathrm{m}^{3}$ this year and 248 egg per station $-24 \mathrm{eggs} / \mathrm{m}^{3}$ - in 2018). It should be also noted the almost lack of spawning activity of mackerel in both Porcupine and the slope in $8 . a\left(48^{\circ} \mathrm{N}\right)$, with only a $7 \%$ and $33 \%$ of the stations being positives for mackerel eggs with an average of 20.67 and 2.29 egg counts/station corresponding to 2.29 and $0.2 \mathrm{eggs} / \mathrm{m}^{3}$ respectively. On the contrary, in $8 . b\left(45^{\circ} N\right)$ the spawning activity was really high, with $82 \%$ of the station being positives for mackerel eggs with the highest egg production too (1 $181 \mathrm{eggs} / \mathrm{station}$ corresponding to $95.91 \mathrm{eggs} / \mathrm{m}^{3}$ ) (Figure 8.6.5.2.3).

### 8.7 Stock Assessment

### 8.7.1 SAM assessment

### 8.7.1.1 Update assessment in 2019

During the 2019 interbenchmark process (ICES IBPNEAMac 2019; ICES, 2019a), a number of changes have been accepted for the NEA mackerel assessment. After identifying a number of potential biases in the RFID dataset, the decision was made to use a sub-set of the available data:

- Only fish recaptured 1 or 2 years after release are now used, in order to avoid the potential bias linked to tag loss or longer term post-tagging mortality.
- Fish tagged at a young age (4 and younger) are excluded from the data base, as they correspond to not fully mature ages, and therefore only a subcomponent of these age classes may be present on the spawning grounds were the tagging survey is carried out.
- The first 2 years of recapture in the tagging program are also excluded, as the volume of the catch scanned was much lower in these first years of the RFID program, and the catches only originates from a limited geographical area.

In addition to this, the SAM model configuration was modified in order to treat the young fish (ages 0 and 1 ) differently from the older fish. While in the previous assessment, there was one common observation variance parameter and one common F random walk variance parameter for all ages, the new assessment now estimates separate parameters for age 0 , age 1 and for older ages.
The interbenchmark process was conducted using the data available for WGWIDE2018 (ICES, 2018d). The WGWIDE2019 assessment was therefore the first update assessment carried out with the new methodology. The update assessment was carried out by fitting the state-space assessment model SAM (Nielsen and Berg, 2014) using the R library stockassessment (downloadable at install_github("fishfollower/SAM/stockassessment")) and adopting the configuration described in the Stock Annex. The assessment is also available on the webpage stockassessment.org (assessment named MackWGWIDE2019v02).
The assessment model is fitted to catch-at-age data for ages 0 to 12 (plus group) for the period 1980 to 2018 (with a strong down-weighting of the catches for the period 1980-1999) and three surveys: (1) the SSB estimates from the triennial Mackerel Egg survey (every three years in the period 1992-2019); (2) the recruitment index from the western Europe bottom trawl IBTS Q1 and Q4 surveys (1998-2018); and (3) the abundance estimates for ages 3 to 11 from the IESSNS survey (2010, 2012-2019). The model also incorporates tagging-recapture data from the Norwegian tagging program (for fish recaptured between 1980 and 2005 for the steel tags time series, and fish recaptured between 2014 and 2018 (age 5 and older at release) for the radio frequency tags time series).

Fishing mortality-at-age and recruitment are modelled as random walks, and there is a process error term on ages 1-11.

The differences in the new data used in this assessment compared to the benchmark assessment were:

- update of the recruitment index until 2018.
- Addition of the preliminary 2019 SSB estimate from the egg survey
- Addition of the 2019 survey data in the IESSNS indices.
- Addition of the 2018 catch-at-age, weights-at-age in the catch and in the stock and maturity ogive, proportions of natural and fishing mortality occurring before spawning.
- $\quad$ The inclusion of the tag recaptures from 2018

Input parameters and configurations are summarized in Table 8.7.1.1.1. The input data are given in Tables 8.7.1.1.2 to 8.7.1.1.9. Given the size of the data base, the tagging data are not presented in this report, but are available on www.stockassessment.org in the data section (files named tag_steel.dat and tag_RFID.dat).

### 8.7.1.2 Model diagnostics

## Parameter estimates

The estimated parameters and their uncertainty estimates are shown in Table 8.7.1.2.1 and Figure 8.7.1.2.1. The model now estimates different observation standard deviations for young fish and for older fish. Reflecting the suspected high uncertainty in the catches of age 0 fish (mainly discards), the model gives a very poor fit to this data (large observation standard deviation). The standard deviation of the observation errors on catches of age 1 is lower, indicating a better fit. For the age 2 and older, the fit to the catch data is very good, with a very low observation standard deviation.

The observation standard deviations for the egg survey and the IESSNS surveys ages 4 to 11 are higher, indicating that the assessment gives a lower weight to the information coming from these surveys compared to the catches. The IESSNS age 3 is a very poorly fitted in the assessment (high observation standard deviation). Overdispersion of the tag recaptures has the same meaning as the observation standard deviations, but is not directly comparable.

The catchability of the egg survey is 1.23, larger than 1, which implies that the assessment considers the egg survey index to be an overestimate. The catchabilities at age for the IESSNS increase from 0.86 for age 3 to 2.14 for age 7 and decreases slightly for older ages. Since the IESSNS index is expressed as fish abundance, this also means that the assessment considers the IESSNS to provide over-estimated abundance values for the oldest ages. The post tagging mortality estimate is higher for the steel tags (around 40\%) than for the RFID tags (around 13\%).

The process error standard deviation (ages 1-11) is moderate as well as the standard deviation of the F random walks.

The catchability parameters for the egg survey, recruitment index and post tagging survival appear to be estimated more precisely than other parameters (Table 8.7.1.2.1). The catchability for the IESSNS have a slightly higher standard deviation, except for the catchability of the IESSNS at age 3 which has a much higher standard deviation. Uncertainty on the observation standard deviations is larger for the egg survey, the IESSNS age 3 and for the recruitment index than for the other observations. Uncertainty on the overdispersion of the RFID tag data is high. The standard deviation on the estimate of process error is low, and the standard deviations for the estimates of $F$ random walk variances of age 0 and 1 are both very high.

The estimated AR1 error correlation structure for the observations from the IESSNS survey age 3 to 11 has a high correlation between the errors of adjacent ages ( $r=0.73$ ), then decreasing exponentially with age difference (Figure 8.7.1.2.2.). This high error correlation implies that the weight of this survey in the assessment in lower than for a model without correlation structure, which is also reflects in the high observation standard deviation for this survey.

There are some correlations between parameter estimates (Figure 8.7.1.2.3):

- Catchabilities are positively correlated (especially for the IESSNS age 4 to 11), and negatively correlated to the survival rate for the RFID tags. This simply represents the fact that all scaling parameters are linked, which is to be expected.
- The observation variance for the IESSNS age 4-11 is positively correlated to the autocorrelation in the errors for these observation. This implies that when the model estimates highly correlated errors between age-groups, the survey is considered more noisy.

## Residuals

The "one step ahead" (uncorrelated) residuals for the catches did not show any temporal pattern (Figure 8.7.1.2.4) except for 2014 for which they were mainly positive for 2014 (modelled catches lower than the observed ones). This may result from the random walk that constraints the variations of the fishing mortality, which prevents the model from increasing the fishing mortality suddenly (which probably happened given the sharp increase in the catches in 2014). Residuals are of a similar size for all ages, indicating that the model configuration with respect to the decoupling of the observation variances for the catches is appropriate.
The residuals for the egg survey show a strong temporal pattern with large positive residuals for the period 2007-2010-2013, followed by large negative residuals in 2016 and 2019. This pattern reflects the fact that the model, based on all the information available, does not follow the recent trend present in the egg survey (with an historical low estimate for 2019) and considers those two last years as large negative observation errors. The strong increase in the observation variance for this survey (see Section 8.7.1.4.2) indicating a poorer fit with the egg survey is related to these two observations which point towards a very different direction as the other observations.

Residuals for the IESSNS indices show an alternation of positive, negative and positive residuals again in the years 2017-2018-2019, which reflect the fact that there is probably a negative year effect in 2018 in this survey. Residuals for the rest of the period year are more balanced.

Residuals to the recruitment index show no particular pattern, and appear to be relatively randomly distributed.

Finally, inspection of the residuals for the tag recaptures (Figure 8.7.1.2.5) did not show any specific pattern for the RFID data. For the steel tags, there is a tendency to have more positive residuals at the end of the period which could indicate that using a constant survival rate for this dataset may not be appropriate.

## Leave one out runs

In order to visualise the respective impact of the different surveys on the estimated stock trajectories, the assessment was run leaving out successively each of the data sources (Figure 8.7.1.2.6).

The run without the RFID recaptures and the run without the recruitment index failed to converge. Making a small change in the model configuration (grouping the F random walk variance of age 1 with the one of the older ages, which did not have a noticeable effect on the stock trajectories for the run using all data source), it was possible to achieve converge for the run without RFID data, but not for the run without the recruitment index. It has therefore not been possible to assess the influence of this index on the assessment.

All leave out one runs showed parallel trajectories in SSB and Fbar. Removing the IESSNS resulted in lower SSB estimates and higher Fbar estimates for the period covered by the survey. On the opposite, removing the egg survey results in a larger estimated stock, exploited with a lower fishing mortality. In both cases, the estimated stock trajectories are well within the confidence interval of the assessment using all data sources. The final assessment seems to make a trade-off between the information coming from the IESSNS which leads to a more optimistic perception of the stock, and the information from the egg survey which suggests a more pessimistic perception of the stock. The run leaving out the RFID data gave a perception of the SSB very similar to the assessment using all data, and slightly higher fishing mortality over the last decade. This is a contrasting situation compared to the 2018 WGWIDE assessment, in which the RFID had a very strong influence on the assessment, and is the consequence of the changes made during the interbenchmark process and listed above. A closer inspection of the run without the RFID data (Figure 8.7.1.2.7) indicates that, although the inclusion of the RFID does not modify sensibly the

SSB trajectory, it does slightly reduce the uncertainty on the SSB estimates (slightly wider confidence bounds without the RFID data).

### 8.7.1.3 State of the Stock

The stock summary is presented in Figure 8.7.1.3.1 and Table 8.7.1.3.1. The stock numbers-at-age and fishing mortality-at-age are presented in Tables 8.7.1.3.2-3. The spawning stock biomass is estimated to have increase almost continuously from just above 2 million tonnes in the late 1990s and early 2000s to 5.2 million tonnes in 2014 and subsequently declined continuously to reach a level just above 4.3 million tonnes in 2018. The fishing mortality has declined from levels between $\mathrm{F}_{\mathrm{pa}}(0.37)$ and $\mathrm{F}_{\lim }(0.46)$ in the mid-2000s to levels just above $\mathrm{F}_{\mathrm{MSY}}$ in 2018. The recruitment time series from the assessment shows a clear increasing trend since the late 1990s with a succession of large year classes (2002, 2005-2006, 2011 and 2016-2017). There is insufficient information to estimate accurately the size of the 2018 year class, estimate is very high but highly uncertain.

There is some indication of changes in the selectivity of the fishery over the last 30 years (Figure 8.7.1.3.2.). In the 1990s, the fishery seems to have had a steeper selection pattern (more rapid increase in fishing mortality with age). Between the end of the 1990s and the end of the 2000s, the selection pattern became less steep (decreasing selection on the ages2-5). After 2008, the pattern changed again towards a steeper selection pattern.

### 8.7.1.4 Additional exploratory runs

### 8.7.1.4.1 Excluding the 2018 estimates from the IESSNS survey

The residual plot for the IESSNS survey suggests a negative year effect in 2018 which is also visible in the survey index (Figure 8.6.3.3). A year effect in a survey corresponds to an anomaly in the catchability of the survey in a given year, that be caused by a range of different factors (poor weather, stock geographic distribution, fish behaviour ...). The reasons for this particular 2018 year effect have not been fully investigated yet. Nonetheless, it seemed worthwhile exploring the effect of removing this particular year from the IESSNS index used in the assessment.

This was done during WGWIDE and was found to make little difference in the outcome of the assessment. There was barely any difference in model parameters when the 2018 IESSNS index was removed (except a small reduction of the observation error variance for the age 3 in the IESSNS). This had no noticeable consequences for the estimated stock trajectories (Figure 8.7.1.4.1.1).

The SAM mackerel assessment includes a correlation structure for the errors in the IESSNS, which effectively means that the model is designed to cope with year effects in that survey (which correspond to errors correlated across age-classes). This results in more accurate estimates of model parameters (no bias due to invalid assumption that the errors are independently distributed). Amongst those parameters, the observation variance for the IESSNS survey are estimated at higher values once the correlation structure is used (ICES, 2017b), reflecting decreasing weight of this survey. A consequence is that the model is rather insensitive to the exclusion a single year of data, as already found in 2018 WGWIDE (ICES, 2018d), and confirmed by this analysis.

### 8.7.1.4.2 Excluding the 2016 and 2019 estimates from the egg survey index

Since 2010, the survey showed a very large expansion of the spawning area to the Northeast (into the Norwegian Sea), the North (south of Iceland) and West (on Hatton bank, see Figure 8.6.1.4). In 2016 and 2019, the survey could not cover the full extension of the spawning, probably leading to an underestimation of the total annual egg production. The areas that could not be covered are assumed to contain only low density of eggs and the conclusion of the MEGS group was that the bias on the SSB index should be rather small. Still, given the strong residual pattern found
for this survey in the assessment (with 2 large negative residuals for 2016 and 2019), it seemed worthwhile investigating the sensitivity of the assessment to these 2 specific survey points.

The mackerel assessment run without the 2016 and 2019 egg survey estimates showed a much better overall fit to the egg survey index (strong decrease in the observation variance, Figure 8.7.1.4.2.1). However, a temporal pattern still remained in the residuals (Figure 8.7.1.4.2.2), which indicates that the assessment still did not completely match the temporal development in the egg survey index. The stock trajectories are slightly modified by the removal of these 2 years in the egg survey (upwards for SSB and downwards for Fbar, Figure 8.7.1.4.2.3). The difference on the final assessment year estimates is $+10 \%$ for SSB and $-7 \%$ for $F_{b a r}$, but much smaller for the earlier years.
Considering the magnitude of the residuals for 2016 and 2019 - reflecting the discrepancy between the recent trend in the assessed SSB and the trend in the egg index - these two data only have a small overall effect on stock trajectories. This reflects the behaviour of the SAM model which automatically weights the data sources. In this case, the egg survey has been downweighted as the new information became more contradictory with the rest of the assessment.

### 8.7.1.5 Quality of the assessment

## Parametric uncertainty

Large confidence intervals are associated with the SSB in the years before 1992 (Figure 8.7.1.3.1 and Figure 8.7.1.5.1). This results from the absence of information from the egg survey index, the down-weighting of the information from the catches and the assessment being only driven by the tagging data and natural mortality in the early period. The confidence intervals become narrower from the early 1990s to the mid-2000s, corresponding to the period where information is available from the egg survey index, the tagging data and (partially) catches. The uncertainty increases slightly in the most recent years and the SSB estimate for 2018 is estimated with a precision of $+/-24 \%$ (Figure 8.7.1.3.1 and Table 8.7.1.3.1). There is generally also a corresponding large uncertainty on the fishing mortality, especially before 1995. The estimate of Fbart-8 in 2018 has a precision of $+/-27 \%$. The uncertainty on the recruitment is high for the years before 1998 (precision of on average $+/-45 \%$ ). The precision improves for the years for which the recruitment index is available ( $+/-30 \%$ ) except for the most recent recruitments ( $+/-40 \%$ ).

## Model instability

The retrospective analysis was carried out for 3 retro years, by fitting the assessment using the 2019 data, removing successively 1 year of data (Figure 8.7.1.5.2). There is a systematic retrospective pattern found in the SSB (which is revised upwards with each new year of data) and the opposite for Fbar. However, given that the RFID series in now composed for only 5 years of recapture data, retrospective instability is to be expected (and retrospective runs removing 4 or more years would be meaningless as only 1 recapture year or none would be available for model fitting).

Recruitment appears to be quite consistently estimated.

## Model behaviour

The realisation of the process error in the model was also inspected. The process error expressed as annual deviations in abundances-at-age (Figure 8.7.1.5.3) shows indications of some pattern across time and ages. There is a predominance of positive deviations in the recent years for ageclasses 5 to 8 . While process error is assumed to be independent and identically distributed, there
is clear evidence of correlations in the realisation of the process error in the mackerel assessment, which appears to be correlated both across age-classes and temporarily.

The temporal autocorrelation can also be visualised if the process error is expressed in term of biomass (process error expressed as deviations in abundances-at-age multiplied by weight at age and summed over all age classes, Figure 8.7.1.5.4). Periods with positive values (when the model globally estimates larger abundances-at-age than corresponding to the survival equation) have been alternating with periods with negative values (19911994 and 2004 and 2006). For the years between 2008 and 2016, the biomass cumulated process error remains positive, and large (reaching in 2013 almost the weight of the catches). The reason for this misbehaviour of the model could not be identified. It should be noted, however, that the magnitude and autocorrelation of the biomass cumulated process error since 2016 is lower than in the previous year's assessment.

### 8.7.2 Exploratory assessments

### 8.7.2.1 Muppet model

Alternative model runs were done with the Muppet model that is a traditional separable catch at age model without any random effects. The model can use tagging data in the objective function and correlation of residuals in age disaggregated survey indices is modelled. The results are described in the working document from Björnsson (2019) presented to WGWIDE, but summarized shortly here.
The data used for tuning are the same as in the adopted assessment (i.e egg survey, pelagic survey, recruitment index and RFID tagging data).

The model setup before 2000 is based on using the catch in numbers data but estimate a scaling factor (1 number on the catches). This scaling factor is supposed to reflect average misreporting. For comparison the adopted assessment does not use the catch data before 2000 and the assessment is only based on tagging data where the level of misreporting depends on estimated tagging mortality.

The estimated "misreporting parameter" in the Muppet model depends on the selection pattern and is higher when selection is estimated separately for the early period.

Other differences between the Muppet and SAM model are:

- The recruitment model in Muppet is similar as if Beverton and Holt or Ricker were used in SAM (RTC3 type model).
- Constraints in fishing mortality (random walk) not implemented.

Different setup of the Muppet model lead to widely different results (Figure 8.7.2.1.1). The same setup as used in the adopted assessment leads to larger estimated stock compared to the adopted assessment. The preferred setup here is thought to use all the tagging data and implement tagloss. This setup leads to smaller stock compared to using limited subset of the tagging data as done in the adopted assessment. As shown in the IBPNEAMac report (ICES, 2019a) observed and predicted tagging data fit reasonably well with this model setup in Muppet.

Recruitment estimates from the Muppet model are very different from those in the assessment model (Figure 8.7.2.1.2) where large part of the recruitment is generated by subsequent deviations in M.

To summarize, the model does not lead to "one correct result", something that would be expected when tuning the model with as disparate and contradictory data as the data for NEA mackerel.

### 8.8 Short term forecast

The short-term forecast provides estimates of SSB and catch in 2020 and 2021, given assumption of the current year's (also called intermediate year) catch and a range of management options for the catch in 2020.

All procedures used this year follow those used in the benchmark of 2014 as described in the Stock Annex.

### 8.8.1 Intermediate year catch estimation

Estimation of catch in the intermediate year (2019) is based on declared quotas and interannual transfers as shown in the text table in Section 8.1.

### 8.8.2 Initial abundances at age

The recruitment estimate at age 0 from the assessment in the terminal assessment year (2018) was considered too uncertain to be used directly, because this year class has not yet fully recruited into the fishery. The last recruitment estimate is therefore replaced by predictions from the RCT3 software (Shepherd, 1997). The RCT3 software evaluates the historical performance of the IBTS recruitment index, by performing a linear regression between the index and the SAM estimates over the period 1998 to the year before the terminal year. The recruitment is then calculated as a weighted mean of the prediction from this linear regression based on the IBTS index value, and a time tapered geometric mean of the SAM estimates from 1990 to the year before the terminal year. The time tapered geometric mean gives the latest years more weight than a geometric mean. This is done because the recent productivity of the stock appears different than in the 1990's.

The weighting calculated by RCT3 was 85 \% (recruitment index) and 15 \% (time tapered geometric mean), which leads to an expected recruitment of 7259 millions.

### 8.8.3 Short term forecast

A deterministic short-term forecast was calculated using FLR (www.flr-project.org). Table 8.8.3.1 lists the input data and Tables 8.8.3.2 and 8.8.3.3 provide projections for various fishing mortality multipliers and catch constraints in 2020.

Assuming catches for 2019 of 834954 kt , F was estimated at 0.21 (below Fmsy) and SSB at 4.39 Mt (above $\mathrm{B}_{\mathrm{pa}}$ ) in spring 2019. If catches in 2020 equal the catch in 2019, F is expected to increase to 0.21 (above $\mathrm{F}_{\mathrm{lim}}$ ) in 2020 with a corresponding increase in SSB to 4.54 Mt in spring 2020 . Assuming an F of 0.21 again in 2021, the SSB will remain at a similar level $(4.47 \mathrm{Mt})$ in spring 2020.

Following the MSY approach, exploitation in 2020 shall be at $\mathrm{F}_{\mathrm{MSY}}(0.23)$, this is equivalent to catches of 922 kt and an increase in SSB to 4.53 Mt in spring 2020 ( $3 \%$ increase). During the subsequent year, SSB is predicted decrease with $3 \%$ to 4.39 Mt in spring 2020.

### 8.9 Biological Reference Points

An Interbenchmark Workshop on the assessment of northeast Atlantic mackerel (IBPNEA-Mac) was conducted during 20182019 (ICES, 2019a) which resulted in the adoption of new reference points for NEA mackerel stock by ICES.

### 8.9.1 Precautionary reference points

$B_{\text {lim }}$ - There is no evidence of significant reduction in recruitment at low SSB within the time series hence the previous basis for Blim was retained. Blim is taken as Bloss, the lowest estimate of spawning stock biomass from the revised assessment. This was estimated to have occurred in 2003; Bloss $=1990000 \mathrm{t}$.
$F_{\text {lim }}$ - Flim is derived from Blim and is determined from the long-term equilibrium simulations as the F that on average would bring the stock to $\mathrm{Blim}_{\mathrm{lim}}$ F $\mathrm{Flim}=0.46$.
$B_{p a}$ - The ICES basis for advice requires that a precautionary safety margin incorporating the uncertainty in actual stock estimates leads to a precautionary reference point $\mathrm{B}_{\mathrm{pa}}$, which is a biomass reference point with a high probability of being above $\mathrm{B}_{\mathrm{lim} .} \mathrm{B}_{\mathrm{pa}}$ was calculated as $B_{\text {lim }}$. $\exp (1.645 \cdot \sigma)$ where $\sigma=0.14$ (the estimate of uncertainty associated with spawning biomass in the terminal year in the assessment, 2017, as estimated in the 2019 intermediate benchmark assessment); $\mathrm{B}_{\mathrm{pa}}=2500000 \mathrm{t}$.
$\boldsymbol{F}_{p a}$-The ICES basis for advice requires that a precautionary safety margin incorporating the uncertainty in actual stock estimates leads to a precautionary reference point $\mathrm{F}_{\mathrm{pa}} . \mathrm{F}_{\mathrm{pa}}$ is the estimate of fishing mortality which is designed to ensure that the true F is above $\mathrm{F}_{\text {lim }}$ with a $95 \%$ probability. Its value is calculated based on $\mathrm{F}_{\text {lim, }}$ whilst taking the assessment uncertainty in F into consideration: Flim ${ }^{*} \exp (1.645 \sigma)$ where $\sigma=0.14$ was the estimated standard deviation of $\ln (\mathrm{F})$ in the final assessment year (2017), this leads to $\mathrm{F}_{\mathrm{pa}}=0.37$.

### 8.9.2 MSY reference points

The ICES MSY framework specifies a target fishing mortality, Fmsy, which, over the long term, maximises yield, and also a spawning biomass, MSY Btrigger, below which target fishing mortality is reduced linearly relative to the SSB $B_{\text {trigger }}$ ratio.

Following the ICES guidelines (ICES, 2017a), long term equilibrium simulations indicated that $\mathrm{F}=0.23$ would be an appropriate $\mathrm{Fmsy}^{\text {marget }}$ as on average it resulted in the highest mean yields in the long term, with a low probability (less than $5 \%$ ) of reducing the spawning biomass below Blim.

The ICES basis for advice notes that, in general, $\mathrm{F}_{\text {mSY }}$ should be lower than $\mathrm{F}_{\mathrm{pa}}$, and MSY $\mathrm{B}_{\text {trigger }}$ should be equal to or higher than $B_{\text {pa. }}$. Simulations indicated that potential values for MSY $B_{\text {trigger }}$ were below $B_{p a}$. Following the ICES procedure MSY Btrigger was set equal to $B_{p a}, 2500000 \mathrm{t}$.

| Updated ICES reference points for NEA mackerel |  |  |  |
| :---: | :---: | :---: | :---: |
| Type |  | Value | Technical basis |
| MSY <br> approach | MSY $\mathrm{B}_{\text {trigger }}$ | 2.50 million tonnes | $\mathrm{B}_{\mathrm{pa}}{ }^{1}$ |
|  | $\mathrm{F}_{\text {MSY }}$ | 0.23 | Stochastic simulations ${ }^{1}$ |
| Precautionary approach | $\mathrm{Blim}^{\text {m }}$ | 1.99 million tonnes | $B_{\text {loss }}$ from 2019 interbenchmark assessment (2003) ${ }^{1}$ |
|  | $\mathrm{B}_{\mathrm{pa}}$ | 2.50 million tonnes | $B_{\text {lim }} \times \exp (1.654 \times \sigma), \sigma_{\text {SSB }}=0.14{ }^{1}$ |
|  | $F_{\text {lim }}$ | 0.46 | F that, on average, leads to $\mathrm{Blim}^{1}$ |
|  | $\mathrm{F}_{\mathrm{pa}}$ | 0.37 | $\mathrm{F}_{\text {lim }} \times \exp (1.654 \times \sigma), \sigma_{\mathrm{F}}=0.14{ }^{1}$ |

${ }^{1} 20182019$ benchmark assessment (ICES, 2019a)

### 8.10 Comparison with previous assessment and forecast

The last available assessment used for providing advice was carried out in 2019 during the IBPNEAMac. The new 2019 WGWIDE assessment gives a slightly different perception of the recent development of the stock (Figure 8.10.1). The SSB trajectory since 2014 has been rescaled slightly upwards, while the estimated $\mathrm{F}_{\mathrm{bar}}$ has been rescaled downwards. The estimated recruitment time series are very similar.

The differences in the 2017 TSB and SSB estimates between the previous and the present assessments are moderate, of 8.3 and $6.9 \%$ respectively. The upward revision of the 2017 fishing mortality estimate is larger, of $-16 \%$.

|  | TSB 2017 | SSB 2017 | Fbar4-8 2017 |
| :--- | :--- | :--- | :--- |
| Values |  |  |  |
| 2019 IBPNEAMac | 5329214 | 4387307 | 0.287 |
| 2019 WGWIDE | 5773203 | 4692164 | 0.241 |
| \% difference | $8.3 \%$ | $6.9 \%$ | $-16.0 \%$ |

The addition of a new year of data has slightly modified the relative weight of the different data sources: the estimated observation standard deviation has increased (although not significantly) both for the IESSNS survey and for the egg survey. This decreasing influence of the 2 surveys on the assessment may be related to the increasing conflict between these two series, the IESSNS indicating record high biomass in 2019 (Figure 8.6.3.2a) while the egg survey index is at its lowest. These changes in the weight of the different data sources can partly explain the revision of stock trajectories. As a result of this change in perception of the stock, small differences are found in the estimated catchabilities for the surveys.

The uncertainty on the parameter estimates has decreased for some parameters (standard deviations of the F random walk for age 0 , and the observation variance for the catches age 2-12, Figure 8.10.2), but increased for others (recruitment variance, and catchability of the IESSNS for ages 4-8). The uncertainty on SSB and Fbart-8 in this year's assessment is in general larger than for the inter-benchmark assessment, especially for the period 2005-2015 (Figure 8.10.3).

The prediction of the mackerel catch for 2018 used for the short-term forecast in the advice given after the interbenchmark was very close to the actual 2018 catch reported for WGIWIDE 2019 and used in the present assessment (text table below). The new assessment produced an estimate of the SSB in 2018 which was just $2.2 \%$ lower than the 2019 IBPNEAMac forecast prediction (ICES, 2019a). The fishing mortality Fbart-8 for 2018 estimated at the WGWIDE 2019 is $14.2 \%$ lower than the value estimated by the short term forecast in the previous assessment. Most of this discrepancy is explained by the revision of the perception of $\mathrm{F}_{\text {bar } 4-8}$ described above.

|  | Catch (2018) | SSB (2018) | $F_{\text {bar4-8 }}(2018)$ |
| :---: | :---: | :---: | :---: |
| 2019 IBPNEAMac forecast | 1000559 t | 4186496 t | 0.28 |
| 2019 WGWIDE assessment | 1026424 t | 4279185 t | 0.24 |
| \% difference | 2.6\% | 2.2\% | -14.3\% |

### 8.11 Management Considerations

Details and discussion on quality issues in this year's assessment is given in Section 8.7 above.
The mackerel in the Northeast Atlantic is traditionally characterised as three distinct 'spawning components': the southern component, the western component and the North Sea component. The basis for the components is derived from tagging experiments (ICES, 1974). However, the methods normally used to identify stocks or components (e.g. ectoparasite infections, blood phenotypes, otolith shapes and genetics) have not been able to demonstrate significant differences between animals from different components. The mackerel in the Northeast Atlantic appears on one hand to mix extensively whilst, on the other hand, exhibit some tendency for homing (Jansen et al., 2013; Jansen and Gislason, 2013). Consequently, it cannot be considered either a panmictic population, nor a population that is composed of isolated components (Jansen and Gislason, 2013).

Nevertheless, stock components are still being used to identify the different spawning areas where mackerel are known to spawn. The trends in the different components is derived from the triennial egg survey in the western and southern area and a dedicated egg survey in the North Sea the year following the western survey.

Since the mid-1970s, ICES has continuously recommended conservation measures for the North Sea component of the Northeast Atlantic mackerel stock (e.g. ICES, 1974; ICES, 1981). The measures advised by ICES to protect the North Sea spawning component (i.e. closed areas and minimum landing size) aimed to promote the conditions that make a recovery of this component possible.

The recommended closure of Division 4.a for fishing during the first half of the year is based on the perception that the western mackerel enter the North Sea in July/August, and remain there until December before migrating to their spawning areas. Updated observations from the late 1990s suggested that this return migration actually started in mid- to late February (Jansen et al., 2012). The EU TAC regulations stated that within the limits of the quota for the western component (ICES Subareas and Divisions 6, 7, 8.a,b,d,e, 5.b (EU), 2.a (non-EU), 12, 14), a certain quantity of this stock may be caught in 4. during the periods 1 January to 15 February and 1 September to 31 December. Up to 2010, $30 \%$ of the Western EU TAC of mackerel (MAC/2CX14-) could be taken in 4.a. From 2011 onwards, this percentage has been set at $40 \%$, in 2015 at $60 \%$ and at $24 \%$ in 2018 and 2019.

The minimum landing size (MLS) for mackerel is currently set at 30 cm for the North Sea and 20 cm in the western area. The historical basis for the setting of minimum landing sizes is described in a working document to WGWIDE in 2015 (Pastoors, 2015). The MLS of 30 cm in the North Sea was originally introduced by Norway in 1971 and was intended to protect the very strong 1969 year class from exploitation in the industrial fishery. The 30 cm later became the norm for the North Sea MLS while the MLS for mackerel in western waters was set at 20 cm . In the early 1990s, ICES recommended that, because of mixing of juvenile and adult mackerel on western waters fishing grounds, the adoption of a 30 cm minimum landing size for mackerel was not desirable as it could lead to increased discarding (ICES, 1990; 1991). A substantial part of the catch of (western) NEA mackerel is taken in ICES division 4.a during the period October until mid-February to which the 30 cm MLS applies even though there is limited understanding on the effectiveness of minimum landing sizes in achieving certain conservation benefits (STECF, 2015).

### 8.12 Ecosystem considerations

An overview of the main ecosystem drivers possibly affecting the different life-stages of Northeast Atlantic mackerel and relevant observations are given in the Stock Annex. The discussion here is limited to recent features of relevance.

## Production (recruitment and growth)

Mackerel recruitment (age 1) has been higher since 2001 compared to previous decades with several very large cohorts (Jansen, 2016). Increasing stock size was suggested to have an effect through density driven expansion of the spawning area into new areas with Calanus in oceanic areas west of the North European continental shelf (Jansen, 2016). There are several indications of a shift in spawning and mackerel recruitment/larvae and juvenile areas towards northern and north-eastern areas preceding the 2016 mackerel spawning (ICES, 2016; Nøttestad et al., 2018). This northerly shift in spawning and recruitment pattern of NEA mackerel seem to have continued also in 2017 (Nøttestad et al., 2018), but has reversed in 2018 (Figure 8.6.2.2).
The recruitment index indicates high recruitment in 2016, 2017 and 2018. For the two first year classes, this is confirmed by the IESSNS, where the incoming 2017-year class has the largest age1 index value recorded in IESSNS and is $150 \%$ larger than the incoming age- 1 cohort in 2017 (ICES, 2018a). In 2019 on the other hand, the incoming 2018-year class was one of the lowest in the entire IESSNS time series (Nøttestad et al., 2019). This may reflect the more south-western distribution of the recruits from the 2018 year class as it was observed in the IBTS-surveys.

During the recent decade, mackerel length- and weight-at-age declined substantially for all ages (Jansen and Burns, 2015; Ólafsdóttir et al., 2015). Growth of 0-3 years old mackerel decreased from 1998 to 2012. Mean length at age 0 decreased by 3.6 cm , however the growth differed substantially among cohorts (Jansen and Burns, 2015). For the 3-8 years old mackerel, the average size was reduced by 3.7 cm and 175 g from 2002 to 2013 (Ólafsdóttir et al., 2015). The variations in growth of mackerel in all ages are correlated with mackerel density. Furthermore, the density dependent regulation of growth from younger juveniles to older adult mackerel, appears to reflect the spatial dynamics observed in the migration patterns during the feeding season (Jansen and Burns, 2015; Ólafsdóttir et al., 2015). Growth rates of the juveniles were tightly correlated with the density of juveniles in the nursery areas (Jansen and Burns, 2015). For adult mackerel (age 3-8) growth rates were correlated with the combined effects of mackerel and herring stock sizes (Ólafsdóttir et al., 2015). Conspecific density-dependence was most likely mediated via intensified competition associated with greater mackerel density.

The growth (mean weights per age group) have slightly increased during the last 34 years for several age groups (ICES, 2018c; ICES, 2019a). However, this does not include the 0-year olds which supports the finding of high abundance at age 0 (Figure 8.5.2.1.).

## Spatial mackerel distribution and timing

In the mid-2000s, summer feeding distribution of Northeast Atlantic mackerel (Scomber scombrus) in Nordic Seas began expanding into new areas (Nøttestad et al., 2016). During 2007-2016 period mackerel distribution range increased three-fold and the centre-of-gravity shifted westward by 1650 km and northward by 400 km . Distribution range peaked in 2014 and was positively correlated to Spawning Stock Biomass (SSB).

After a mackerel stock expansion during the feeding season in summer from 1.3 million $\mathrm{km}^{2}$ in 2007 to at least 2.9 million $\mathrm{km}^{2}$ in 2014, mainly towards western and northern regions of the Nordic seas (Nøttestad et al., 2016), a slight decrease in distribution area of mackerel in the Nordic Seas was observed in 2017 and 2018 with 2.8 million square kilometres (Nøttestad et al., 2017; ICES, 2018a). The mackerel distribution slightly increased to 2.9 million $\mathrm{km}^{2}$ in 2019 (Nøttestad et al., 2019). The mackerel was more patchily distributed within the survey area in 2019 and 2017 than in 2018. Mackerel had a more eastern distribution in 2019 and 2018 than in 20142017 (ICES, 2018a; Nøttestad et al., 2019). This difference in distribution primarily consists of a marked biomass decline in the west, and particularly in Greenland waters but also in Icelandic waters. Geographical distribution of the 2016 cohort at age 0 and 1 extended more to the north than normally, including latitude $6071^{\circ} \mathrm{N}$ along the coast and offshore areas of Norway based on various survey data and fishing data (Nøttestad et al., 2018).

## Spatial mackerel distribution related to environmental conditions

Ólafsdóttir et al. (2018) analysed the IESSNS data from 2007 to 2016 with the following results: Mackerel was present in temperatures ranging from $5^{\circ} \mathrm{C}$ to $15^{\circ} \mathrm{C}$, but preferred areas with temperatures between $9^{\circ} \mathrm{C}$ and $13^{\circ} \mathrm{C}$ according to univariate quotient analysis. Generalized additive models showed that both mackerel occurrence and density were positively related to location, ambient temperature, meso-zooplankton density and SSB, explaining $47 \%$ and $32 \%$ of deviance, respectively. Mackerel relative mean weight-at-length was positively related to location, day-of-year, temperature and SSB, but not with meso-zooplankton density, explaining $40 \%$ of the deviance. Geographical expansion of mackerel during the summer feeding season in Nordic Seas was driven by increasing mackerel stock size and constrained by availability of preferred temperature and abundance of meso-zooplankton. Marine climate with multidecadal variability probably impacted the observed distributional changes but were not evaluated. Our results were limited to the direct effects of temperature, meso-zooplankton abundance, and SSB on distribution range during the last two decades $(1997-2016)$ and should be viewed as such.
In the 2019 IESSNS a marked change in the spatial distribution of mackerel was observed with lower densities of mackerel in the western distribution areas (East Greenland and Iceland) as compared to 2017 (see Figures 8.6.3.6a and b). It is not clear what causes this distributional shift, but the SST were $1-2^{\circ} \mathrm{C}$ higher in the western and south-western areas as compared to a 20 years mean (19992009), and substantially lower zooplankton concentrations in Icelandic and Greenland waters in 2019 than 2018, might partly explain such changes (ICES, 2018a, Nøttestad et al., 2019).

## Trophic interactions

There are strong indications for interspecific competition for food between NSS-herring, blue whiting and mackerel (Huse et al., 2012). According to Langøy et al. (2012), Debes et al. (2012), Óskarsson et al. (2015) and Bachiller et al. (2016), the herring may suffer from this competition, as mackerel had higher stomach fullness index than herring and the herring stomach composition is different from previous periods when mackerel stock size was smaller. Langøy et al. (2012) and

Debes et al. (2012) also found that mackerel consumed wider range of prey species than herring. Mackerel may thus be thriving better in periods with low zooplankton abundances. Feeding incidence increased with decreasing temperature as well as stomach filling degree, indicating that feeding activity is highest in areas associated with colder water masses (Bachiller et al., 2016). A bioenergetics model developed by Bachiller et al. (2018) estimated that the NEA mackerel, NSS herring and blue whiting can consume between 122 and 135 million tonnes of zooplankton per year (2005-2010) This is higher than that estimated in previous studies (e.g. Utne et al., 2012; Skjoldal et al., 2004). NEA mackerel feeding rate can consequently be as high as that of the NSS herring in some years. Geographical distribution overlap between mackerel and NSS herring during the summer feeding season is highest in the south-western part of the Norwegian Sea (Faroe and east Icelandic area) (Nøttestad et al., 2016; 2017; Ólafsdóttir et al., 2018). The spatiotemporal overlap between mackerel and herring was highest in the southern and south-western part of the Norwegian Sea in 2018 and 2019 (ICES, 2018a, Nøttestad et al., 2019). This is similar as seen in previous years (Nøttestad et al., 2016; 2017). A change was seen in the northern Norwegian Sea in 2019 where we had some overlap between mackerel and herring (mainly 2013and 2016- year classes) (Nøttestad et al., 2019). There was, on the other hand, practically no overlap between NEA mackerel and NSSH in the central and northern part of the Norwegian Sea in 2018 and previous years, mainly because of very limited amounts of herring in this area (ICES, 2018a).

There seem to be rather limited spatial overlap between marine mammals and mackerel during summers in the Nordic Seas (Nøttestad et al., 2019; Løviknes, 2019). There is spatial overlap between killer whales and mackerel in the Norwegian Sea, and killer whales are actively hunting for mackerel schools close to the surface during summer (Nøttestad et al., 2014). The increase of 0 - and 1-groups of NEA mackerel found along major coastlines of Norway both in 2016 and 2017 (Nøttestad et al., 2018) and 2018 (Bjørdal, 2019), has created some interesting new trophic interactions. Increasingly numbers of adult Atlantic bluefin tuna (Thynnus thunnus), with an average size of approximately 200 kg , have been documented to feed on 0-group mackerel from the 2016, 2017-year classes during the commercial bluefin tuna fishery in Norway (Nøttestad et al., 2017b; Boge, 2019). Additionally, the new situation of numerous 0 - and 1-group mackerel in Norwegian coastal waters in 2018 (Bjørdal, 2019), have created favourable feeding possibilities for larger cod, saithe, marine mammals and seabirds in these waters. Repeated stomach samples from several species document that smaller sized mackerel is now eaten by different predators in northern waters $\left(60-70^{\circ} \mathrm{N}\right)$ (Bjørdal, 2019). Although much fewer 1-groups of NEA mackerel was found along the coast in Norway during the IESSNS 2019 (Nøttestad et al., 2019), the Atlantic bluefin tuna are still indeed targeting schools of 1-group mackerel during their intense feeding migration in Norwegian waters.

Table 8.2.4.1. Overview of major existing regulations on mackerel catches.

| Technical measure | National/International level | Specification | Note |
| :---: | :---: | :---: | :---: |
| Catch limitation | Coastal States/NEAFC | 2010-2018 | Not agreed |
| Management strategy (EU, NO, FO agreement London 12. Oct. 2014) | European (EU, NO, FO) | $\text { If SSB >= 3.000.000t, F = } 0.24$ <br> If SSB is less than 3.000 .000 t , F $=0.24$ * SSB/3.000.000 <br> TAC should not be changed more than 20\% <br> A party may transfer up to $10 \%$ of unutilised quota to the next year | Not agreed by all parties |
| Management strategy with updated reference points 2017 (EU, NO, FO agreement London 11. Oct. 2017) | European (EU, NO, FO) | $\text { If SSB }>=2.570 .000 t, F=0.21$ <br> If SSB is less than 2.570 .000 t , F $=0.21 * S S B / 2.570 .000$ <br> TAC should not be changed more than $+25 \%$ or $-20 \%$ <br> A party may transfer up to $10 \%$ of unutilised quota to the next year <br> A party may fish up to $10 \%$ beyond the allocated quota, that have to be deduced from next years quota. | Not agreed by all parties |
| Minimum size (North Sea) | European (EU, NO, FO) | 30 cm in the North Sea |  |
| Minimum size (all areas except North Sea) | European (EU, NO) | 20 cm in all areas except North Sea | 10\% undersized allowed |
| Minimum size | National (NO) | 30 cm in all areas |  |
| Catch limitation | European (EU, NO, FO) | Within the limits of the quota for the western component (6, 7, 8.a-b,d,e, 5.b (EC), 2.a (nonEC), 12, 14), a certain quantity may be taken from 4.a but only during the periods 1 January to 15 February and 1 October to 31 December. |  |
| Area closure | National (UK) | South-West Mackerel Box off Cornwall | Except where the weight of the mackerel does not exceed $15 \%$ by liveweight of the total quantities of mackerel and other marine organisms onboard which have been caught in this area |
| Area limitations | National (IS) | Pelagic trawl fishery only allowed outside of 200 m depth contours around Iceland and/or 12 nm from the coast. |  |

| Technical measure | National/International level | Specification | Note |
| :--- | :--- | :--- | :--- |
| National catch limita- <br> tions by gear, semester <br> and area | National (ES) | $28.74 \%$ of the Spanish national <br> quota is assigned for the trawl <br> fishery, $34.29 \%$ for purse <br> seiners and $36.97 \%$ for the arti- <br> sanal fishery | Since 2015, the trawl fish- <br> ery has the individual <br> quotas assigned by vessel. |
| Discard prohibition | National (NO, IS, FO) | All discarding is prohibited for <br> Norwegian, Icelandic and Faro- <br> ese vessels |  |
| European | From 2015 onwards a landing <br> obligation for European Union <br> fisheries is in place for small pe- <br> lagics including mackerel, horse <br> mackerel, blue whiting and her- <br> ring. | There are de minimis ex- <br> emptions for mackerel <br> caught in bottom-trawl <br> fisheries in the North <br> Western Waters (EC |  |
| 2018/2034) and in the |  |  |  |

Table 8.6.4.1. Overview of numbers released in the different RFID tagging experiments, and numbers recaptured per year (year 2019 show update per 1th September to demonstrate ongoing process). Recaptures from experiments and recapture years used in 2019 stock assessment, based on decisions in the ICES IBPNEAMac 2019 (ICES, 2019) is outlined and marked grey. However, note that these numbers also include recaptures from some factories excluded in the final estimation of tag table used in the stock assessment 2019 (see Slotte, 2019 -WD12- and Tables 8.6.4.2-3). Note also that during tagging off Ireland 2018 two experiments were carried out on same vessel, where the one named Ireland2018-2 was based on fishing and handling mackerel in the same way as with the older steel tag time series (manual jigging and release directly at starboard side, instead of automatic jigging and release through pipes at port side as in rest of RFID time series) for comparison of recapture rates.

Table 8.6.4.3. Overview of numbers of RFID tagged mackerel recaptured per factory per year. The number of recaptures used in 2019 stock assessment, based on decisions in the ICES IBPNEAMac 2019 (ICES 2019) and evaluation of efficiency of the scanners (WD 12), is outlined and marked grey. Note that two factories, DK01 Sæby and IC03 Höfn, are shown in this table, but not in Table 8.6.4.2 with biomass scanned, to demonstrate that they have had a few recaptures although not functioning properly.

| Input data types and characteristics: |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Name | Year range | Age range | Variable fr | year to year |
| Catch in tonnes | 1980-2018 |  | Yes |  |
| Catch-at-age in numbers | 1980-2018 | 0-12+ | Yes |  |
| Weight-at-age in the commercial catch | 1980-2018 | 0-12+ | Yes |  |
| Weight-at-age of the spawning stock at spawning time. | 1980-2018 | 0-12+ | Yes |  |
| Proportion of natural mortality before spawning | 1980-2019 | 0-12+ | Yes |  |
| Proportion of fishing mortality before spawning | 1980-2019 | 0-12+ | Yes |  |
| Proportion mature-atage | 1980-2019 | 0-12+ | Yes |  |
| Natural mortality | 1980-2019 | 0-12+ | No, fixed at |  |
| Tuning data: |  |  |  |  |
| Type | Name | Year range |  | Age range |
| Survey (SSB) | ICES Triennial Mackerel and Horse Mackerel Egg Survey | $\begin{aligned} & 1992,1995,1998 \\ & 2007,2010,2013 \end{aligned}$ | $\begin{aligned} & \text { 2001, } 2004, \\ & 2016,2019 . \end{aligned}$ | Not applica SSB) |
| Survey <br> (abundance index) | IBTS Recruitment index (log transformed) | 1998-2018 |  | Age 0 |
| Survey <br> (abundance index) | International Ecosystem Summer Survey in the Nordic Seas (IESSNS) | 2010, 2012-2019 |  | Ages 3-11 |
| Tagging/recapture | Norwegian tagging program | Steal tags : 1980 2006 (recapture RFID tags : 2013 2018 (recapture | elease year) ars) <br> elease year) ar) | Ages 5 and at release) |
| SAM parameter configuration: |  |  |  |  |
| Setting | Value | Description |  |  |
| Coupling of fishing mortality states | 1/2/3/4/5/6/7/8/8/8/8/8/8 | Different F states for ages 0 to 6 , one same $F$ state for ages 7 and older |  |  |
| Correlated random walks for the fishing mortalities | 0 | F random walk of different ages are independent |  |  |
| Coupling of catchability parameters | 0/0/0/0/0/0/0/0/0/0/0/0/0 | No catchability parameter for the catches |  |  |

|  | $\begin{aligned} & \hline \text { 1/0/0/0/0/0/0/0/0/0/0/0/0 } \\ & \text { 2/0/0/0/0/0/0/0/0/0/0/0/0 } \\ & \text { 0/0/0/3/4/5/6/7/8/9/10/10/0 } \end{aligned}$ | One catchability parameter estimated for the egg <br> One catchability parameter estimated for the recruitment index <br> One catchability parameter for each age group estimated for the IESSNS (age 3 to11) |
| :---: | :---: | :---: |
| Power law model | 0 | No power law model used for any of the surveys |
| Coupling of fishing mortality random walk variances | 1/2/3/3/3/3/3/3/3/3/3/3/3 | Separate F random walk variances for age 0 , age 1 and a same variance for older ages |
| Coupling of log abundance random walk variances | 1/2/2/2/2/2/2/2/2/2/2/2/2 | Same variance used for the log abundance random walk of all ages except for the recruits (age 0) |
| Coupling of the observation variances | $\begin{gathered} \text { 1/2/3/3/3/3/3/3/3/3/3/3/3 } \\ \text { 0/0/0/0/0/0/0/0/0/0/0/0/0 } \\ \text { 4/0/0/0/0/0/0/0/0/0/0/0/0 } \\ 0 / 0 / 0 / 5 / 6 / 6 / 6 / 6 / 6 / 6 / 6 / 6 / 0 \end{gathered}$ | Separate observation variances for age 0 and 1 than for the older ages in the catches <br> One observation variance for the egg survey <br> One observation variance for the recruitment index <br> 2 observation variances for the IESSNS (age 3 and ages 4 and older) |
| Stock recruitment model | 0 | No stock-recruiment model |
| Correlation structure | "ID", "ID", "ID", "AR" | Auto-regressive correlation structure for the IESSNS index, independent observations assumed for the other data sources |

Figure 8.4.2.4. NE Atlantic Mackerel. Commercial catches in 2018, quarter 4.

Figure 8.5.2.1. NE Atlantic mackerel. Weights-at-age in the catch.

Figure 8.5.2.2. NE Atlantic mackerel. Weights-at-age in the stock.

Figure 8.5.3.1. NE Atlantic mackerel. Proportion of mature fish at age.

Figure 8.6.1.1. Mackerel egg production by half rectangle for period 2 (Feb 5th - Mar 3rd). Filled blue circles represent observed values, filled red circles represent interpolated values, blue crosses represent observed zeroes, red crosses interpolated zeroes.

Figure 8.6.1.2. Mackerel egg production by half rectangle for period 3 (Mar 4th - Apr 12th). Filled blue circles represent observed values, filled red circles represent interpolated values, blue crosses represent observed zeroes, red crosses interpolated zeroes.

Figure 8.6.1.3. Mackerel egg production by half rectangle for period 4 (Apr 13th - May 3rd). Filled blue circles represent observed values, filled red circles represent interpolated values, blue crosses represent observed zeroes, red crosses interpolated zeroes.

Figure 8.6.1.4. Mackerel egg production by half rectangle for period 5 (May 4th - June 5th). Filled blue circles represent observed values, filled red circles represent interpolated values, blue crosses represent observed zeroes, red crosses interpolated zeroes.

Figure 8.6.1.5. Mackerel egg production by half rectangle for period 6 (June 6 th -30 th). Filled blue circles represent observed values, filled red circles represent interpolated values, blue crosses represent observed zeroes, red crosses interpolated zeroes.

Figure 8.6.1.6. Mackerel egg production by half rectangle for period 7 (July 1st - 31st). Filled blue circles represent observed values, filled red circles represent interpolated values, blue crosses represent observed zeroes, red crosses interpolated zeroes.

Figure 8.6.1.7. Provisional annual egg production curve for mackerel in the western spawning component. The curves for 2007, 20102013 and 2016 are included for comparison.

Figure 8.6.1.8. Provisional annual egg production curve for mackerel in the southern spawning component for 2019. The curves for 2007, 2010, 2013 and 2016 are included for comparison.

Figure 8.6.1.9. Combined mackerel TAEP estimates ( ${ }^{*} \mathbf{1 0}^{13}$ ) - 1992-2019.

Figure 8.6.2.1. Demersal trawl survey data used to derive the abundance index of age-0 mackerel. (a) Trawl sample locations in the fourth quarter (Q4, October - November, blue dots); (b) trawl sample locations in the first quarter (Q1, January - March, light blue dots); (c) number of samples by year and quarter; and (d) depth.

Figure 8.6.2.2. Spatial distribution of mackerel juveniles at age 0 in October to March. Left) average for cohorts from 19982018; and Right) 2018 cohort. Mackerel squared catch rates by trawl haul (circle areas represent catch rates in $\mathrm{kg} / \mathrm{km} 2$ ) overlaid on modelled squared catch rates per $10 \times 10 \mathrm{~km}$ rectangle. Each rectangle is coloured according to the expected squared catch rate in percent of the highest value for that year. See Jansen et al. (2015) for details.

Figure 8.6.2.3. Index of mackerel juveniles at age $\mathbf{0}$ in October to March proxied by annual integration of square root of expected catch in demersal trawl surveys (Blue lines). See Jansen et al. (2015) for details.

Figure 8.6.3.1. Fixed predetermined trawl stations (shown for CTD and WP2) included in the IESSNS 28th June - 5th August 2019. At each station a 30 min surface trawl haul, a CTD station ( $0-500 \mathrm{~m}$ ) and WP2 plankton net samples ( $0-200$ m depth) were performed. The colour codes, Árni Friðriksson (purple), Finnur Fríði (black), Kings Bay and Vendla (blue), Eros (green) and Ceton (red).

Figure 8.6.3.2a. Estimated total stock biomass (TSB) of mackerel from StoX (black dots), Nøttestad et al. (2016) (red dots) and IESSNS cruise reports (blue diamonds) 2007-2019. The error bars represent approximate $90 \%$ confidence intervals.

IESSNS,TSN

Figure 8.6.3.2b. Estimated total stock numbers (TSN) of mackerel from StoX (black dots) for the years 2010, 20122019. The error bars represent approximate $90 \%$ confidence intervals

Figure 8.6.3.3. Catch curves. Each cohort is marked by a uniquely coloured line that connects the estimates indicated by the respective ages.

Figure 8.6.3.4a. Age distribution in proportion represented as a) \% in numbers and b) \% in biomass of Northeast Atlantic mackerel in 2019.

Figure 8.6.3.4b. Mackerel numbers by age from the IESSNS survey in 2019, excluding North Sea. Boxplot of abundance and relative standard error (CV) obtained by bootstrapping with 500 replicates using the StoX software (http://www.imr.no/forskning/prosjekter/stox/nb-no).

Figure 8.6.3.5. Internal consistency of the mackerel abundance index from the IESSNS surveys including data from 2012 to 2019, excluding North Sea in 2019. Ages indicated by white numbers in grey diagonal cells. Statistically significant positive correlations ( $p<0.05$ ) are indicated by regression lines and red cells in upper left half. Correlation coefficients ( $r$ ) are given in the lower right half.

Figure 8.6.3.6a. Mackerel catch rates from surface trawl hauls (circle size represents catch rate $\mathbf{i n ~} \mathbf{k g} / \mathbf{k m} 2$ ) overlaid on mean catch rate per standardized rectangle ( $1^{\circ}$ lat. x $2^{\circ}$ lon.) from the IESSNS survey in 2019.

Figure 8.6.3.6b. Annual distribution of mackerel proxied by the relative distribution of mean mackerel catch rates per standardized rectangles ( $2^{\circ}$ lat. x $4^{\circ}$ lon.), from Multpelt 832 pelagic trawl hauls at predetermined surface trawl stations. Colour scale goes from white $(=0)$ to red (= maximum value for the given year).

Figure 8.6.4.1. Distribution (per ICES rectangle) of RFID tagged mackerel (20112019), catch biomass scanned for RFID tagged mackerel (2012-2018) and corresponding numbers of recaptured mackerel (20122018). Darker colours mean higher density. Note that the maps give an overview of the total material, whereas details on actual data used on the stock assessment is given in Tables 8.4.6.13. Positions of factories with RFID scanners are shown as green dots on map (Irish scanners are not operational).

Figure 8.6.4.2. Overview of the relative year class distribution among RFID tagged mackerel per release year, compared with the numbers scanned and recaptured in year 1 and $\mathbf{2}$ after release of the same year classes. Only release years used in the mackerel assessment based on decisions in the ICES IBPNEAMac 2019 meeting (ICES, 2019a) are shown. Not that it was also decided to only use ages 511 in updated assessments, and limits for this age span is marked for each release year.

Figure 8.6.4.3. Trends in aggregated abundance index from RFID tag-recapture data. Comparison between the subset used in WGWIDE 2018 (release year 2011+, all recapture years, ages 211) versus the subset used in the updated WGWIDE 2019 assessment (release year 2013+, only recapture year 1 and 2 after release, ages 5-11), and the change using these subsets but the 2019 updated tag data set (updated with 2017 release data, and recaptures in 2018 from 2016 and 2017 releases). Method used is Chapman Lincoln-Peterson estimator described in IBPNEAMac 2019 report (ICES, 2019a).

Figure 8.6.4.4. Trends in year class abundance from RFID tag-recapture data. Method used is Chapman Lincoln-Peterson estimator described in IBPNEAMac 2019 report (ICES, 2019a). Shown is only the subset data used in current assessment; release year 2013+, recapture year 1 and 2 after release and ages 5-11.

Figure 8.6.5.2.1. Centre of gravity for mackerel acoustic distribution from PELACUS 0313-19. The plot is showing the relative cumulative NASC distribution starting in the southern part and ending at the inner part of the Bay of Biscay.

Figure 8.6.5.2.2: Mackerel abundance and biomass estimates by age group in ICES Divisions 8c. and 9.a during PELACUS 0319 (left). Upper right panel: mackerel mean weight (grams, blue line) and total biomass (thousand tonnes red line) estimated in PELACUS 201319; lower right: mackerel mean length (cm, blue line) and total abundance (million fish, red line) estimated in PELACUS 201319.

Figure 8.6.5.2.3: Mackerel subsurface egg distribution (no eggs/m³) as recorded by CUFES during PELACUS 0319.

Figure 8.7.1.2.1. NE Atlantic mackerel. Parameter estimates from the SAM model (and associated confidence intervals) for the WGWIDE 2019 update assessment. top left: estimated standard deviation for the observation errors, top centre: estimated overdispersion for the errors on the tag recaptures, top right: standard deviation for the processes, bottom: survey catchabilities and post-release survival of tagged fish.

Figure 8.7.1.2.2. NE Atlantic mackerel. Estimated AR1 error correlation structure for the observations from the IESSNS survey age 3 to 11 .

Figure 8.7.1.2.3. NE Atlantic mackerel. Correlation between parameter estimates from the SAM model for the WGWIDE 2018 update assessment

Figure 8.7.1.2.4. NE Atlantic mackerel. One Step Ahead Normalized residuals for the fit to the catch data (catch data prior to $\mathbf{2 0 0 0}$ in blue rectangle were not used to fit the model). Blue circles indicate positive residuals (observation larger than predicted) and filled red circles indicate negative residuals.

Figure8.7.1.2.5. NE Atlantic mackerel. One step ahead residuals for the fit to the recaptures of tags in the final assessment. The $x$-axis represents the release year, and the $y$-axis is the number of years between tagging and recapture. Each panel correspond to a given age at release. Blue circles indicate positive residuals (observation larger than predicted) and filled red circles indicate negative residuals.

Figure 8.7.1.2.6. NE Atlantic mackerel. Leave one out assessment runs. SAM estimates of SSB and F bar, $^{\text {b }}$ for assessments runs leaving out one of the observation data sets.

Figure 8.7.1.2.7. NE Atlantic mackerel. Leave one out assessment run excluding the RFID tagging data with confidence intervals for both runs (WGWIDE assessment in blue, run with RFID in red, overlap between both confidence intervals in purple).

Figure 8.7.1.3.1. NE Atlantic mackerel. Perception of the NEA mackerel stock, showing the SSB, $\mathrm{F}_{\text {bar }} 4-8$ and recruitment (with 95\% confidence intervals) from the SAM assessment.

Figure 8.7.1.3.2. NE Atlantic mackerel. Estimated selectivity for the period 1990 to 2018, calculated as the ratio of the estimated fishing mortality-at-age and the $\mathrm{F}_{\text {bar }} 48$ value in the corresponding year.

Figure 8.7.1.4.1.1. NE Atlantic mackerel. Influence of the 2018 IESSNS survey on the output of the assessment. Comparison of stock estimates from the 2019 WGWIDE assessment, the 2019 WGWIDE assessment without the 2018 IESSNS index.

Figure 8.7.1.4.2.1. NE Atlantic mackerel. Comparison of estimated model parameters for the WGWIDE 2019 update assessment and the same assessment performed excluding the 2016 and 2019 egg survey indices.

Figure 8.7.1.4.2.2. NE Atlantic mackerel. Residuals for the egg survey index in the assessment run excluding the 2016 and 2019 egg survey estimates.

Figure 8.7.1.4.2.3. Influence of the 2016 and 2019 egg survey estimates on the output of the assessment. Comparison of stock estimates from the 2019 WGWIDE assessment, the 2019 WGWIDE assessment without the 2016 and 2019 egg indices.

Figure 8.7.1.5.1. NE Atlantic mackerel. Uncertainty (standard deviation of the log values) of the estimates of SSB and $\mathrm{F}_{\text {bar }}$ from the SAM for the 2018 WGWIDE assessment.

Figure 8.7.1.5.2. NE Atlantic mackerel. Analytical retrospective patterns (3 years back) of SSB, $\mathrm{F}_{\mathrm{bar}} 48$ and recruitment from the WGWIDE 2018 update assessment.

Figure 8.7.1.5.3. NE Atlantic mackerel. Process error expressed as annual deviations of abundances at age, for the 2019 WGWIDE assessment and from the 2019 interbenchmark assessment.

Figure 8.7.1.5.4. NE Atlantic mackerel. Model process error expressed in biomass cumulated across age-group for the 201 WGWIDE assessment and for the 2019 interbenchmark assessment.

Figure 8.7.2.1.1. Development of spawning stock from different configurations of the Muppet model compared to the adopted SAM setup from WGWIDE 2019.

Figure 8.7.2.1.2. Estimated number of age $\mathbf{2}$ fish from SAM (blue), muppet (black) and catch of the year-class at age $\mathbf{2}$ to 11 (red).

Figure 8.10.1. NE Atlantic mackerel. Comparison of the stock trajectories between the 2019 WGWIDE assessment and the 2019 IBPNEAMac (ICES, 2019a).

Figure 8.10.2. NE Atlantic mackerel. Comparison of model parameters and their uncertainty for the 2019 WGWIDE and the 2019 IBPNEAMac (ICES, 2019a).

Figure 8.10.3. NE Atlantic mackerel. Comparison of the uncertainty on estimates of SSB and F bar $^{\text {for }}$ for WGWIDE 2019 update assessment and the 2019 IBPNEAMac (ICES, 2019a).
