INTRODUCTION

There are five native fish species in freshwater in Iceland. These are the salmonid species, Atlantic salmon (*Salmo salar*), brown trout (*Salmo trutta*) and arctic charr (*Salvelinus alpinus*). The other two are, European eel (*Anquilla anquilla*) and three-spined sticklebacks (*Gasterosteus aculeatus*). Of these species salmon has the highest economic value.

The fishing season in Icelandic rivers is at the maximum of 105 days in the period from 20th of May to 30th of September. In rivers where salmon fishery is mainly based on release of reared salmon smolts the fishing season can be extended to 120 days and throughout October with permission from the Directorate of Fisheries (Fiskistofa). The daily fishing period is usually 12 hours, and the fishery must be closed for 84 hours each week. In most Icelandic rivers rod and line is the only fishing gear allowed. A fixed number of rods are used in each river. The fishing effort has remained almost unchanged since 1970. Each Fishery association needs to make a plan that outlines the management strategy. The management plan needs approval by the Directorate of Fisheries after a review by the Institute of Freshwater Fisheries.

Net fishery is almost exclusively in the largest glacial rivers. In the net fishery gillnets are the most common fishing method and draftnet are used at few locations for brown trout and Arctic charr. The weekly net fishing period is from Tuesday morning at 10 AM to Friday evening at 10 PM. The weekend closure is to reduce fishery and allow fish migration to the up rivers regions.

There has been a general ban on ocean salmon fishing in Icelandic waters since 1932. An exception to that were few localities with coastal fishery at the coast of west Iceland (Vesturland) (Figure 1). At these localities coastal gillnets were used set from land. These fishing rights were permanently bought out in 1997 by fishery associations in nearby rivers and with governmental support. This was possible since salmon caught by anglers are of much higher value than salmon caught in the net fishery. All salmon harvested in Iceland is in freshwater and mostly based on single stock fishery.

The fishing rights go with the ownership of the land adjacent to the rivers. The landowners are usually farmers. All the landowners of the fishing rights in a river system have by law to form a fishery association, which manages the exploitation of the fish stocks, within the frame set by the law. Usually the rivers fishery association rents or leases the fishing rights to angling syndicates, angling clubs or directly to anglers. The entire riverbank is accessible to the

limited number of rod fishermen that have fishing permit each day. Most rivers have fishing lodges with high quality accommodation.

The catch is recorded in special logbooks in the fishing lodges. The logbook recording system was established in 1946. At the end of the fishing season the logbooks from every river are gathered and statistical information are processed by the Institute of Freshwater Fisheries. The results are sent back to the fisheries associations as well as new logbooks before the next fishing season.

Catch statistics from Icelandic rivers for the 2009 fishing season have now been processed and the main results are summarized in this report. This work is based on Gudbergsson (2010), Lax- og silungsveiðin 2009, a report from the Institute of Freshwater Fisheries (in Icelandic). The salmon trout and charr statistics have been compiled this way since 1974.

METHODS

Iceland is divided into statistical regions regarding to salmon catches (Figure 1). Information on the catch is summarized in tables for each region. The results from all regions are then combined for the whole country. The catch statistics for each river is summarized by fishing gear used. The harvesting methods used are rod and line, gillnets or draft-nets. The number of fish released (catch and release) from the rod fisheries are recorded. In previous years ocean ranching harvest has also been summarised. However, there has not been any release of smolts for commercial ocean ranching of salmon since 1998.

By tradition, the weight of freshwater fish in Iceland was measured in pounds where 1 pound = 500 g. In 1999 this was changed to kg and the accuracy of 0,1 kg was anticipated. Fish length is measured to the nearest cm. For each fish, date of catch, pool name and number, type of bait, catch-and-released, as well as the fisherman is recorded in the logbook. Fishing pools are commonly numbered in the logbooks for ease of computer processing.

The salmon catch can be divided by weight into grilse (1SW, one sea winter) and salmon (2SW, two sea winter). Males up to 4 kg and females up to 3.5 kg are grilse (one sea winter) and larger fish are salmon (two sea winter). This deviation into sea age has been confirmed with aging by scales. Salmon with more than 2 winters at sea are rare in Iceland and repeated spawning has been in low percentages in later years.

Brown trout and Arctic charr are caught in many rivers as a by-catch with the salmon. In other rivers these are the most dominant and targeted fish species. In some rivers brown trout and Arctic charr are the dominant species at certain parts of the rivers especially at slow flowing areas at the lower parts of the rivers. In this report stationary trout and sea-trout were combined, and the same applies for sea-run Arctic charr and stationary Arctic charr.

In the rod fishery catch-and-release has been increasing in popularity usually on voluntarily basis by the anglers but in few rivers catch and release is the only allowed fishing method. Many rivers have fly fishing only and bag limit of different magnitude is common. In most recent years, anglers have been encouraged by the Institute of Freshwater Fisheries, the Federation of Icelandic river owners and the Association of Icelandic angling clubs to release two-sea winter salmon in order to protect the two-sea winter salmon stock component that have steadily declined in number since the mid 1980s. The catch statistics is processed for both the total catch including catch and released and the catch landed in numbers of fish and weight.

In Iceland the rod catch in few rivers is based on release of hatchery reared salmon smolts. The catch in these rivers were close to 19 thousand fish in 2009 was 25,4% of the total rod catch. The catch in these rivers was recorded separately since catch figures are often used as a measure of stock abundance of wild salmon.

RESULTS

The salmon catch in 2009

A total of 74.408 salmon were caught in rod fisheries in Icelandic rivers in 2009 where of 17.514 (23,5%) was released and the catch landed (caught and retained) was 56.894 salmon (Table 1). The catch landed by weight was 142.988 kg. In the rod fishery the catch of grilse (1SW) were 52.413 fish (92,1%) and 121.461 kg and 4.481 salmon (7,9%) (2SW) weighing 21.527 kg. Of the total number of released fish 13.161 (71,1%) were grilse and 4.356 (24,9 %) salmon. Of the statistical regions the highest number of fish was caught in the rod fishery in the Vesturland region 23.047 fish where off 3.890 were released and the catch landed was 19.228 fish and 45.709 kg. There were fewer fish recorded in other areas (Table 1).

The catch in the net fishery was 9.607 fish and 27.323 kg in total. The highest number of fish was caught in the Sudurland region, 9.225 fish (Table 2). Of the net catch 8.285 and 19.430 kg was grilse (1SW) and 1.322 and 7.890 kg was salmon (2SW).

The total combined salmon catch landed (rod and nets) in Iceland 2009 was 66.501 fish and 170.311 kg, there of 60.698 (91,2%) were 1SW and 5.803 (8,8%) 2SW. The total 1SW catch was 140.894 kg and the 2SW catch was 29.417 kg (Table 3).

The total number of brown trout caught in rod fishery was 49.192 fish, 6.963 were released and the catch landed was 42.229 fish and 44.975 kg (table 4). The total number of Arctic charr in the rod fishery was 32.919 fish, 4.193 was released and the catch landed was 28.726 fish and 19.692 kg.

The salmon rod catch in 2009 decreased by 9.716 fish (11,5%) from the 2008 salmon season (table 5; figure 2). The total rod catch in 2009 was 50,1% higher than the average catch in the 35 years period from 1974 to 2008. The salmon catch in the net fishery was 204 fish (2,2%) higher than the catch in 2008 but 21,2% lower than the average catch in the period from 1974-2008 (Table 5, Figure 3).

In 2009 the rod catch in rivers where the catch is mainly based on releases of hatchery reared smolts was 18.884 fish that is 25,4% of the total catch and the catch was close to 44 tonnes. The rod catch of wild salmon in 2009 was 55.524 fish that was the highest recorded catch of wild salmon caught in rod fishery (Table 5, figure 3). In total 29,9% of the rod catches was released.

No commercial ocean ranching activities have been operating since 1998. In previous years, substantial activities of ocean ranching with Atlantic salmon was operated in Iceland reaching up to 168 thousand fish caught in 1993 as the highest catch (harvest) (Table 5; Figure 4).

The highest number of salmon caught in rod fishery was in River Ytri-Rangá 10.749 fish with River Eystri-Rangá in second place with 4.237 fish and River Midfjardará in third place with 3.962 fish. The list of top 10 salmon rivers is shown in table 6. The top 3 list for catch landed was the same for Ytri-Rangá and Eystri-Rangá but Blanda was in the third place.

The top 10 list of brown trout is shown in table 7 and the top 10 list of Arctic charr is shown in table 8. Since 1987, the catch of brown trout has increased with record catch in 2005 (Figure 5). The catch of Arctic charr have been increasing for the past three years after a low catch in 2007 (Figure 6).

The rod catch records for individual rivers are listed by statistical areas in tables 9-15. The salmon catch in most Icelandic rivers are listed in table 16 for the period from 1974-2009 including average catch, maximum and minimum catch in the period. The rod catch for brown trout from 1987-2009 is listed in table 17 and for Arctic charr in table 18.

The catch in the net fishery divided by species, rivers and regions is listed in table 19. The highest catch was in River Thjórsá with 5.034 salmon. River Thjorsá is a glacial river in South Iceland.

Age compositions of the salmon catch

The sea-age composition of salmon is shown in figure 7. The figure includes the rivers with yearly catch records since 1970 and includes 88% of the average the annual salmon catch. It is worth noticing that after high catch in the 1980s the catch of 1SW salmon decreased after 1979 and increased after 1985. The 2SW salmon showed similar pattern until 1980 but opposite to the improving catch of 1SW fish the 2SW salmon stock component have shown almost a steady decline since the mid 1980s. This is of major concern and anglers are kindly asked to release 2SW females in order to prevent the 2SW component from over fishing and to conserve the 2SW genetic resource in the salmon stocks.

Catch and release in the rod fishery has increased from 1996 when first recorded and was 23,5% of the total rod catch in 2009 but 29,9% of the wild salmon (Figure 8). Catch and release was 20,0% of the total grilse (1SW) fish but 25,8% of the wild grilse (Figure 9). The proportion of catch and release of salmon (2SW) was 49,3% in total but 56,3 of the wild fish.

DISCUSSION

Since 1932 there has been a general ban on ocean fishery for salmon in Icelandic waters with the exception of few locations with coastal fishery. The number of nets used in river has been decreasing due to lease of nets and buy-out of fishing rights, by anglers and river owners. Now the fishing rights in coastal areas have been bought-out permanently with support form the government. Since the 1998 fishing season all salmon were harvested in freshwater. The number of rods allowed and used in Icelandic salmon rivers has been almost the same since 1970. With stable effort the catch can to large extent be used as an indicator for the size of the salmon run. It can also be seen from the catch statistics that the salmon catch in rivers in the same area show similar fluctuations.

The proportion of 2SW fish is usually higher in rivers in the north and northeast Iceland than in the south and southwest regions. Since 1981-1983 the number of 2SW salmon has been declining. This happened although the sex ratio of the run is stable with close to 65% females for MSW and 20% for 1SW for the period from 1973. That relates to higher mortality at the second year at sea in the later years (Gudbergsson and Gudjonsson 2003). The reasons for this is not clear but this seems to be connected to environmental factors in the ocean (Gudjonsson et al. 1995) that are most likely poor conditions at the feeding grounds for salmon at their second year at sea. These changes has effected the catch in rivers with high proportion of 2SW salmon.

There are considerable fluctuations between years in the salmon catch in Iceland. Usually salmon catch in rivers in the same region fluctuate together. The size of the salmon run depends on the number of smolts produced in each river and their survival at sea. It seems to be that common factors affect the production of smolts in the rivers in the same area and also the return rate from the ocean. Climatic factors are of greatest importance and significant correlation has been found between the catch of grilse and ocean temperature at the time the smolts are migrating in the spring or early summer (Scarnecchia 1984; Antonsson et al. 1996).

The exploitation rate in the rod fisheries, in Icelandic rivers, has been estimated to be between 30-80% (Gudjonsson 1986). Recent information on exploitation in the rod fishery indicates that it can, in some rivers, be 50-60% for 1SW salmon and 60-80% for 2SW salmon(Gudjonsson et al. 1996, Jónsson et al. 2008). In rivers with fish counters it has been shown that the rod catch reflects the changes in stock size. Further studies on exploitation and the size of the spawning stock in Icelandic salmon rivers are needed.

The brown trout catch was the second highest on record. Catch of Arctic charr has, on the other hand been decreasing from 2001 to 2007 but are increasing again for all fishing areas combined. However, catch of Arctic charr has decrease in many rivers in southwest Iceland. The reasons for the decline in catch of Arctic charr are not known but can possibly relate to global warming. The mechanism for this is not fully understood and needs further studies.

Anglers are encouraged to record the trout and charr catch in the same manner as the salmon catch i.e. record each fish with information on length weight and sex of each fish. The catch records give valuable information on fluctuation in salmon stocks and stock compositions.

The continuous decline in the 2SW salmon component is of major concern. The Institute of Freshwater Fisheries has encouraged the Fisheries associations and the authorities to protect 2SW salmon.
