INTRODUCTION

There are five native fish species in freshwater in Iceland. These are the salmonid species, Atlantic salmon (*Salmo salar*), brown trout (*Salmo trutta*) and arctic charr (*Salvelinus alpinus*). The other two are, European eel (*Anquilla anquilla*) and three-spined sticklebacks (*Gasterosteus aculeatus*). Of these species salmon has the highest economic value.

The fishing season in Icelandic rivers is 3 1/2 months during the period from 20th of May to 30th of September. The daily fishing period is 12 hours, between sunset to dawn, and fishing is always closed between 3 AM to 7 AM. In most Icelandic rivers rod and line is the only fishing gear allowed. Only a fixed number of rods are used in each river as decided by the Directorate of Freshwater Fisheries. In the early 1970s when the number of rods allowed in each river was decided a rule of thumb of 1fish/day/rod, on the average was applied. The fishing effort has remained almost unchanged for the past 30 years.

Net fishery is almost exclusively in the largest glacial rivers. In the net fishery gillnets are the most common fishing method and draftnet are used on few places. The weekly net fishing period is from Tuesday morning at 10 AM to Friday evening at 10 PM. The weekend closure is to allow fish migration to the up rivers regions.

There has been a general ban on ocean salmon fishing in Icelandic waters since 1932. An exception to that were 5 localities in the western part of Iceland (Vesturland) (Figure 1). At these localities coastal gillnets were used. These fishing rights were permanently bought out in 1998 by fishery associations in nearby rivers and with governmental support. This was possible since salmon caught by anglers are of much higher value than salmon caught in the net fishery. All salmon harvested in Iceland is in freshwater and mostly based on single stock fishery.

The fishing rights go with the ownership of the land adjacent to the rivers. The landowners are usually farmers. All the landowners of the fishing rights in a river system have by law to form a fishery association, which manages the exploitation of the fish stocks, within the frame set by the law. Usually the fishery association rents or leases the fishing rights to angling clubs or directly to anglers. The entire riverbank is accessible to the limited number of rods allowed. Most rivers have fishing lodges with high quality accommodation.

The catch is recorded in special logbooks in the fishing lodges. The logbook recordings were established in 1946. At the end of each fishing season the logbooks from every river are gathered and statistical information are processed by the Institute of Freshwater Fisheries. The results are sent back to the fisheries associations as well as new logbooks before the next fishing season.

Statistics from Icelandic rivers for the 2006 fishing season have now been processed and the main results are summarized in this report. This work is based on Gudbergsson (2007), Lax-og silungsveiðin 2006, a report from the Institute of Freshwater Fisheries (in Icelandic). Statistics have been compiled this way since 1974.

METHODS

Iceland is divided into statistical regions regarding salmon catches (Figure 1). Information on the catch in each region is summarized in tables. The results from all regions are then combined for the whole country. The catch statistics for each river is summarized by fishing gear used. The harvesting methods used are rod and line, gillnets or draftnets. In previous years ocean ranching harvest has also been summarised. However, there has not been any release of smolts for commercial ocean ranching of salmon since 1998.

By tradition, the weight of freshwater fish in Iceland was measured in pounds where 1 pound = 500 g. Before the 1999 fishing season this was changed to kg and the accuracy of 0,1 kg was anticipated. Fish length is measured to the nearest cm. For each fish, date of catch, pool name and number, bait and catch and released, as well as of the fisherman is recorded in the logbook. Fishing pools are commonly numbered in the logbooks for ease of computer processing.

The salmon catch can be divided by weight into grilse (1SW, one sea winter) and salmon (2SW, two sea winter). Males up to 4 kg and females up to 3.5 kg are grilse and larger fish are salmon. This deviation in sea age has been confirmed with aging by scales. Salmon with more than 2 winters at sea are rare in Iceland and repeated spawning has been in low percentages in later years.

Brown trout and arctic charr are caught in many rivers as a by-catch with the salmon. In other rivers these are the most dominant species. In some rivers brown trout and arctic charr are the

dominant species at certain areas of the rivers especially at slow flowing areas at the lower parts of the rivers. In this report stationary trout and sea-trout were combined, and the same applies for sea-run arctic charr and stationary arctic charr.

In the rod fishery catch-and-release has been increasing in popularity and is on voluntarily basis by the anglers. In most recent years, anglers have been encouraged by the Institute of Freshwater Fisheries, the Federation of Icelandic river owners and the Association of Icelandic angling clubs to release two-sea winter salmon in order to protect the two-sea winter salmon stock component that have steadily declined in number since the mid 1980s. The catch statistics is processed for both the total catch including catch and released and the catch landed.

RESULTS

The catch in 2006

A total of 45.545 salmon were caught in rod fisheries in Icelandic rivers in 2006 where of 8.735 (19,2%) was released and the catch landed (caught and retained) was 36.810 salmon (Table 1). The catch landed was 96.744 kg by weight. In the rod fishery the catch of grilse (1SW) were 32.244 fish and 74.502 kg and 4.566 salmon (2SW) weighing 22.242 kg. Of the released fish 5.785 (15,2%) were grilse and 2.850 (39,3%) salmon. Of the statistical regions the highest number of fish was caught in the rod fishery was in Vesturland 16.125 fish where off 1.964 was released and the catch landed 14.161 fish and 34.534 kg. There were lower catch recorded in other areas (Table 1).

The catch in the net fisheries was in total 5.953 fish and 16.544 kg. The highest number of fish was caught in Suðurland, 5.661 fish (Table 2). Of the net catch 4.455 and 13.876 kg was grilse (1SW) and 1.498 and 2.2668 kg was salmon (2SW). There were no reports of harvest from ocean ranching in 2006.

The total combined salmon catch landed (rod and nets) in Iceland 2006 was 42.763 fish and 113.288 kg where off 36.699 were 1SW and 6.064 2SW. The 1SW catch was 88.378 kg and 2SW catch was 24.910 kg (Table 3).

The total number of brown trout caught in rod fishery was 42.704 fish where off 8.204 were released and the catch landed 34.500 fish and 38.350 kg (table 4). The total number of Arctic

charr in rod fishery was 29.704 fish where off 846 was released and the catch landed 28.858 fish and 22.358 kg.

The salmon catch in 2006 decreased from 2005 by 9.623 fish (17,4%) from the 2005 salmon season (table 5; figure 2). The catch in 2006 was 27,5% higher than the average catch in the 32 years period from 1974 to 2005. The catch in 2006 was the 7.th highest in the period. The salmon catch in the net fishery was 21,2%) lower than the catch in 2005 and the catch was close to the half of the average catch in the period from 1974-2005 (Table 5, Figure 3).

No ocean ranching activities have been since 1998. In previous years, substantial activities of ocean ranching with Atlantic salmon was operated in Iceland reaching up to 168 thousand fish caught in 1993 (Table 5; Figure 4).

The highest number of salmon caught in rod fishery was in River Ytri-Rangá 4.459 fish with Selá in second place with 2.726 fish and Eystri-Rangá in third place with 2.471 salmon. The list of top 10 salmon rivers is shown in table 6. The top 3 list for catch landed was Ytri-Rangá, Eystri-Rangá and Norðurá.

The top 10 list of brown trout is shown in table 7 and the top 10 list of Arctic charr is shown in table 8. Since 1987, the catch of brown trout has increased with record catch in 2005 (Figure 5). The catch if Arctic charr have been decreasing since 2001 (Figure 6).

The rod catch records for individual rivers are listed by statistical areas in tables 9-15. The salmon catch in most Icelandic rivers are listed in table 16 in the period form 1974-2006 including average catch, maximum and minimum catch in the period. The rod catch for brown trout from 1987-2006 is listed in table 17 and for Arctic charr in table 18.

The catch in the net fishery divided by species, rivers and regions is listed in table 19. The highest catch was in River Þjórsá that is a glacial river in Southwest Iceland.

Age compositions of the salmon catch

The sea-age composition of salmon is shown in figure 7. The figure includes the rivers with yearly catch records since 1970 and includes at the average 88% of the annual salmon catch. It is worth noting that after high catch in the 1980s the catch of 1SW salmon decreased after 1979 and improved after 1985. The 2SW salmon showed similar pattern but instead of improving like the 1SW fish the 2SW salmon stock component have shown a steady decline

since the mid 1980s. This decline in number of 2SW salmon continued in 2006. This is of concern and anglers are kindly asked to release 2SW females in order to prevent the 2SW component from over fishing and to conserve the 2SW genetic resource. If the decline of 2SW fish will continue declining at the same rate as in previous years it will be almost distinct in 2020.

DISCUSSION

Since 1932 there has been a general ban on ocean fishery for salmon in Icelandic waters with the exception of few locations with coastal fishery. The number of nets used in river has been decreasing due to lease of nets and buy-out of fishing rights, by anglers and river owners. Now the fishing rights in coastal areas have been bought-out permanently with support form the government. Since the 1998 fishing season all salmon were harvested in freshwater. The number of rods allowed and used in Icelandic salmon rivers has been almost the same for the past 36 years. With stable effort the catch can to large extent be used as an indicator for the size of the salmon run. It can also be seen from the catch statistics that the salmon catch in rivers in the same area show similar fluctuations.

The proportion of 2SW fish is usually higher in rivers in the north and northeast Iceland than in the south and southwest. Since 1981-1983 the number of 2SW salmon has been declining. This happens although the sex ratio of the run is stable with close to 65% females for MSW and 20% for 1SW for the period from 1973. That relates to higher mortality at the second year at sea in the later years (Gudbergsson and Gudjonsson 2003). The reasons for this is not clear but this seems to be connected to environmental factors in the ocean (Gudjonsson et al. 1995) that are most likely poor conditions at the feeding grounds for salmon at their second year at sea. These changes have more effects to the catch in rivers with high proportion of 2SW salmon.

There are considerable fluctuations between years in the salmon catch in Iceland. Usually salmon catch in rivers in the same region fluctuate together. The size of the salmon run depends on the number of smolts produced in each river and their survival at sea. It seems to be that common factors affect the production of smolts in the rivers in the same area and also the return rate from the ocean. Climatic factors are of greatest importance and significant correlation has been found between the catch of grilse and ocean temperature at the time the smolts are migrating in the spring or early summer (Scarneccchia 1984; Antonsson et al. 1996).

The exploitation rate in the rod fisheries, in Icelandic rivers, has been estimated to be between 30-80% (Gudjonsson 1986). Recent information on exploitation in the rod fishery indicates that it can, in some rivers, be 50-60% for 1SW salmon and 60-80% (Gudjonsson et al. 1996). In rivers with fish counters it has been shown that the rod catch reflects the changes in stock size. Further studies on exploitation and the size of the spawning stock in Icelandic salmon rivers are needed.

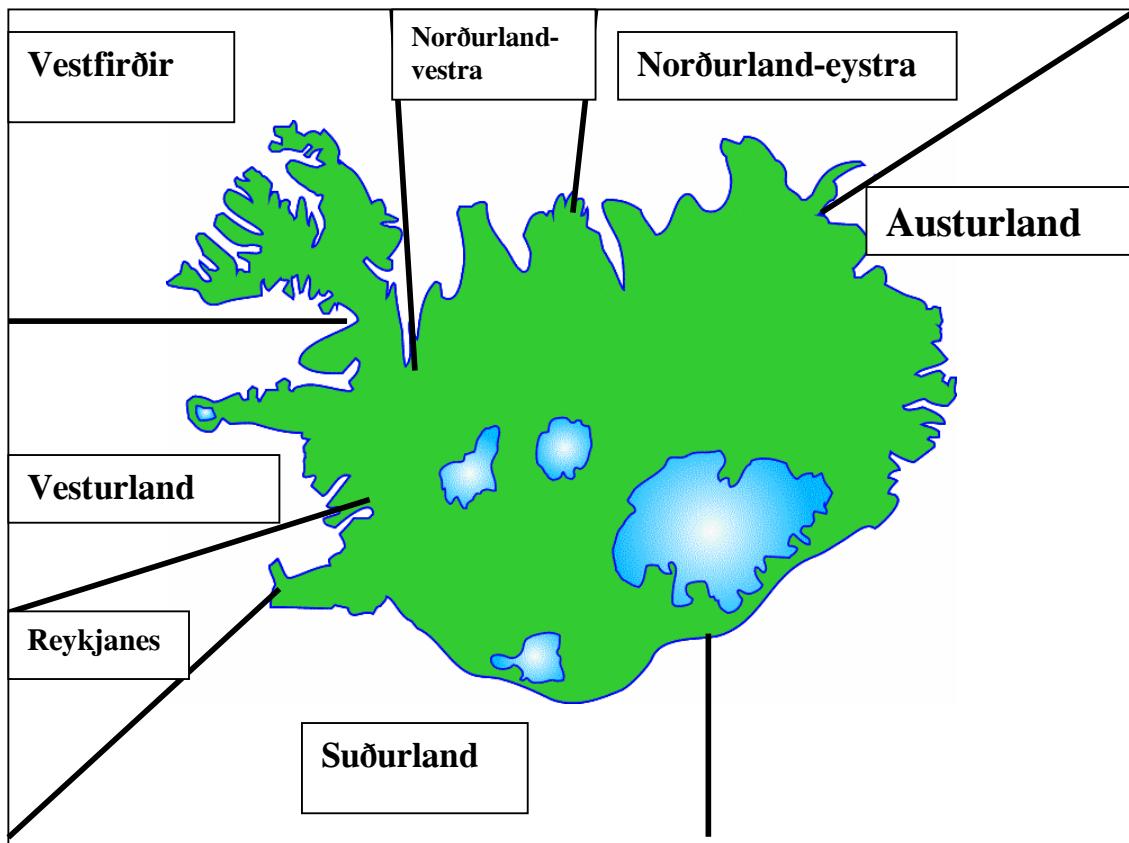

The numbers of brown trout increased with record catch in 2005. Catch of Arctic charr have, on the other hand been decreasing during the past five years. The reasons for the decline in catch of Arctic charr is not known but can possibly be related to global warming. This needs further studies.

Anglers are encouraged to record the trout and charr catch in the same manner as the salmon catch i.e. record each fish with information on length weight and sex of each fish. The catch records give valuable information on fluctuation in salmon stocks and stock compositions. The catch is also an indicator on the prospects of catch in rivers and for evaluation the price of fishing licences.
